Abstract

Montmorillonite (MMT) clays are 2:1 layered structures which in natural state may allocate different hydrated cations such as $M-nH_2O$ ($M= Na, Ca, Fe, etc.$) in its interlayer space. Depending on the capability for ion sorption, these materials are interesting for environmental remediation. In this work we experimentally study the Co sorption in a natural Na-MMT using UV-visible spectrometry and XRD on semi-oriented samples, and then analyze the sorption ability of this clay by means of *ab initio* calculation performed on pristine MMT. The structural properties of Na-MMT and Co-adsorbed MMT, and the hyperfine parameters at different atomic sites were analyzed and compared with the experimental ones for the first, and for the case of the hyperfine parameters, presented for the first time for the last. The theoretical predictions based on total energy considerations confirm that Co incorporation replacing Na is energetically favorable. Also, the basal spacing d_{001} experimentally obtained is well reproduced.

1- Introduction

From the beginning of the industrial revolution, environmental pollution by heavy metals appeared as a direct consequence, and its reversal represents a challenge for modern life. In this scenario pollutants generation and the deposition controls constitute a very important topic due to the negative effects that these elements could cause both on the human health and the environmental quality. Among the mechanisms used for heavy metal removal from effluents, ion exchange allows the use of low cost and environmental friendly materials, like clay minerals and its derivatives (modified clays that enhance the sorption process of the sorbent material)¹⁻³. Among them, Montmorillonite (MMT), a 2:1 clay mineral, is one of the most promising candidates for decontamination and disposal of wastewater with high-level heavy metal cation content, due to its relatively high specific area and cation exchange capacity^{4, 5}. Cobalt is one of the toxic metals affecting the environment. It is widely present in effluents and is originate from different human activities⁶. Its origin is connected with urban storm-water runoff coming from electronic, electroplating, paints and pigments,

1
2
3 mining, metallurgical and nuclear industries (principally from wastes released from
4 pressurized water nuclear power reactors and from medical applications)⁶⁻¹⁰. Because
5 it can affect human health and the environment its removal from effluents is essential<sup>6-
6 11</sup>.

7
8
9 Some studies were performed testing the efficiency of Co sorption in natural
10 and modified MMT^{4,12-24}. The results indicated that the MMT systems can sorb and
11 retain Co depending on the system itself and the physical and chemical conditions.
12 Although the main expected sorption mechanisms in clays are cationic exchange and
13 surface complexation, sorption mechanisms of Co in MMT are still not clear.
14
15

16
17 Between the experimental techniques used to enlighten the mechanisms
18 involved in metal/clay complexation, Nuclear Magnetic Resonance (NMR) became an
19 important tool due to its high sensitivity to the local environment of the atoms and the
20 chemical bonds. Clay layers were previously studied with this technique using ²⁵Mg,
21 ²⁷Al and ²⁹Si as probe atoms²⁵⁻³², whereas for the clay interlayer and swelling behavior,
22 the studies were performed using ¹¹³Cd, ¹³³Cs, and ²³Na probes³³⁻³⁷.
23
24

25
26 Computational quantum simulations have proven to be a suitable tool for
27 understanding the microscopic processes that conduct to the physical and chemical
28 properties of materials. Beyond the simplifications that are made in comparison to the
29 complexity of real materials, they can lead to a better understanding of individual
30 processes involved. Recently *ab-initio* calculations within the Density Functional Theory
31 (DFT) were used to investigate the mechanisms involved in metal sorption on clays³⁸⁻⁴²
32 and especially in MMT⁴³⁻⁵¹. Within this theory some well-tested codes have
33 implemented the determination of the hyperfine parameters⁵²⁻⁵³. In the present work a
34 combined DFT and experimental study for Co sorption in MMT is reported. The
35 calculations are discussed in term of the energetic and structural features
36 accompanying the Na to Co interlayer exchange in pristine MMT. The electronic
37 properties of MMT and Co sorbed MMT are also analyzed.

43
44 The paper is organized as follows: in Section 2 a brief description of the system
45 is given. In Section 3, the experimental methods and the results for the determination
46 of the Co²⁺ sorption are presented. Section 4 describes the models and computational
47 details of the *ab-initio* calculation. In Section 5 the results of the calculations are shown.
48 This section is divided in three subsections: a- the results concerning the energy
49 formation and cell elongation, b- the predicted hyperfine characterization, and c- the
50 comparison with experimental data obtained from literature. Finally, Section 6 is
51 reserved to the conclusions.

2- The system under study.

The MMT structure could be described as a 2:1 phyllosilicate constituted by a laminar structure with an elongated cell along the *c* axis having a triclinic unit cell with space group P1. The layers consist of an octahedral sheet linked with two tetrahedral sheets sharing apical oxygen atoms. The ((Al/Mg)O₆) units form the octahedron layer sandwiched by two layers of (SiO₄) tetrahedrons. In the interlayer region different cations can be allocated, such as Na and Co, with different hydration degrees. The interactions between layers are supposed to be weak. Pristine Na-MMT have as chemical formula Na[(MgAl₃O₈(OH)₄ (Si₈O₁₂)]₂ + m(H₂O). Co-sorbed MMT structure, labeled as Co-MMT, was generated by replacing the Na⁺ with Co²⁺ ions linked with the corresponding H₂O molecules, as will be detailed in the next sections. In Figure 1 it can be seen the starting structure before internal atomic position relaxation for the case m=4 with one Na per unit cell. A second (Na+ 4H₂O) unit and some ((Al/Mg)O₆) units in the neighbor unit cell in the *a* axis direction are depicted for clarity.

3- Experimental

The Co²⁺ sorption experiments were performed using a natural Na-MMT from Río Negro State, Argentina. The sorption studies were performed in batch conditions (V=25 ml), using a Co²⁺ initial concentration of 100 mg/l (obtained after dissolving the corresponding masses of CoCl₆H₂O, provided by Sigma Co.), a solid/liquid ratio of 1 g/l, pH=6 and a contact time of 24 h. Sorption experiments were performed in duplicate.

After the sorption experiment, the liquid and solid phases were separated by centrifugation. The solid phase was dried at 60 °C and stored in a desiccator for its posterior characterization. The remaining Co²⁺ concentration in the liquid phase was determined and from this value the sorbed Co²⁺ was obtained. Co²⁺ determination was performed using a UV-visible spectrometer, following the methodology proposed by Sandell⁵⁴.

The structure changes of the solid phase after the Co-sorption experiments were determined by XRD technique. Partial X-ray diffraction patterns of semi-oriented clays were collected using a Philips 3020 equipment, operating to 35 mA and 40 kV, with Cu K α radiation, from 2° to 10° (2 theta), with 0.02° stepping angle and 10 s/step.

The results of the Co²⁺ sorption experiments confirm that Co²⁺ ions were sorbed into the samples. The sorption percentage for this cation resulted as high as 80±2 %. Before and after the sorption process, XRD analyses were carried out for oriented

1
2
3 samples in order to determine the d_{001} parameter (Figure 2). The obtained results also
4 indicate that after sorption experiments Co incorporation in the interlayer was
5 produced, due to an expansion in the c-axis direction. For the determination of the d_{001}
6 distance, Voight functions were fitted to the XRD spectra. In the case of the sample
7 before the Co^{2+} sorption procedures, two Voight functions were used to take into
8 account the high asymmetry of the corresponding peak. The determined d_{001} distance
9 for Co-MMT was 15.71 ± 0.06 Å while the corresponding for the natural Na-MMT was
10 12.58 ± 0.04 Å and 13.55 ± 0.07 Å, resulting in a high enlargement of the interlayer
11 spacing.

18 **4. Modeling and computational details**

19
20
21 Natural samples of MMT may have different low concentrations of impurities
22 (such as Fe, Ca), and also cation exchange between Si, Al and Mg. The effect of such
23 defects in macroscopic structures is out of the scope of this study. The starting atomic
24 positions for the *ab-initio* calculations for the Na-MMT and Co-MMT in combination with
25 the different hydration states were taken from the work of Pirillo et al.⁴⁶ with lattice
26 parameters $a = 5.2584$ Å $b = 8.7669$ Å $c = 12.8511$ Å and $\beta = 95.3443$. Co-MMT structure
27 was generated by replacing the Na with Co atoms. For the initial m-H₂O units atomic
28 positions we considered starting from symmetric distributions with the H pointing
29 outward the corresponding cation as can be seen in Fig. 1.
30
31
32
33

34 Following the ideas of Berghout et al.⁴⁵ and the studied performed by Pirillo et
35 al.⁴⁶ for the simulated Na-MMT, we considered three different Na
36 concentration/hydration states: *a*- One Na^+ atom surrounded by four H₂O in the unit cell
37 (NaM1); *b*- Two Na^+ atoms, each one of them surrounded by two H₂O (NaM2); and *c*-
38 Two Na^+ atoms, each one of them surrounded by four H₂O (NaM3). For the simulated
39 Co-MMT we considered the case of two Co^{2+} atoms, each one surrounded by six H₂O
40 in the unit cell (CoM1). For each one of the models, refined atomic positions and lattice
41 constants were obtained as explained below.
42
43
44
45

46 All the simulations of the electronic structure were performed within DFT. So, as
47 starting step the density functional first-principles simulations were performed based on
48 the numerical Linear Combination of Atomic Orbitals (LCAO) method as implemented
49 in the Siesta Code⁵³. The calculations have been carried out within the Generalized
50 Gradient Approximation (GGA), using the functional parametrized by Perdew, Burke
51 and Ernzerhof (PBE) to simulate the electronic exchange and correlation potentials⁵⁵.
52 All the core electrons were replaced by *ab-initio* norm-conserving pseudopotentials
53
54
55
56
57
58
59
60

generated using the Troullier-Martins scheme⁵⁶, in the Kleinman-Bylander fully non-local separable representation⁵⁷. The pseudopotentials were generated scalar-relativistically. The size of the basis set chosen was double- ζ plus polarization for the valence states of all the atoms. An equivalent plane wave cutoff of 200 Ry was used to represent the charge density. During geometry optimizations, a 7Å k-grid cutoff for all the Brillouin zone integrations was used. For the structural optimizations, the atomic positions were allowed to relax until the maximum component of the force on any atom was smaller than 0.01 eV/Å, and the maximum component of the stress tensor was smaller than 0.0001 eV/Å³. Finally, the whole internal atomic positions and lattice parameters a , b , c , α , β and γ were relaxed according to the method described above.

Once optimized the atomic positions and cell parameters with the above described method, they were used as input files for the codes available in Quantum ESPRESSO package⁵². The electronic correlation and exchange terms were calculated using the same GGA-PBE functionals. Interaction of valence electrons with nuclei and core electrons were treated by the projector augmented-wave (PAW) method⁵⁸. The energy cutoff for the plane-wave basis set was fixed to 60 Ry and the electron density of 550 Ry. A Monkhorst and Pack⁵⁹ k-point grid of $2 \times 2 \times 2$ was used to sample the first Brillouin zone of the cells. The simulation of NMR parameters was performed with the gauge including projector augmented wave (GIPAW) approach^{60,61}.

IV. Results and Discussion

a- Formation energy and cell elongation.

The calculated lattice parameters and d_{001} values after optimization of the initial parameters of the different cell considered are listed in Table I. From this table and Fig. 2 it can be seen that the experimental and theoretically predicted d_{001} for the Co-MMT are in good agreement. The lattice was strongly expanded in the c direction after the procedure from an initial value of $c=12.851$ Å to the final $c=15.842$ Å were all the internal forces and the cell stress are nearly zero. With the final lattice constants, the resulting d_{001} resulted 15.81 Å, which should be compared with the experimentally obtained $d_{001\text{exp-Co}} = 15.5 \pm 0.6$ Å. Regarding the Na-MMT structures, the resulting d_{001} obtained values are: for NaM1 $d_{001\text{NaM1}} = 12.89$ Å; for NaM2 $d_{001\text{NaM2}} = 12.74$ Å; and for NaM3 $d_{001\text{NaM3}} = 14.19$ Å. These results can help to distinguish which model is closer to the experimental sample. The d_{001} for the case of two Na atoms with 8 H₂O (4 H₂O for each Na) NaM3 is much higher than those obtained in this work 12.58 ± 0.4 Å and

1
2
3 13.55 ± 0.07 Å. So, NaM3 does not reproduce well the sample before the Co²⁺
4 sorption. Regarding the models that take into account 4 molecules of H₂O, NaM1 and
5 NaM2, on the basis of the d₀₀₁ it is not easy to reveal the more appropriate model. Both
6 structures give d₀₀₁ values close to one of the experimentally obtained 12.58 ± 0.4 Å,
7 thus describing well enough part of the Na-MMT sample, but strictly comparing the
8 obtained numbers, together with the obtained lattice parameters, the NaM2 is closer. It
9 must be mentioned that in real samples coexistence of different hydration states can
10 occur. This effect have been observed and discussed in previous works⁶³. As it was
11 mentioned, in our samples two Voight functions were needed to take into account the
12 asymmetry of the XRD peak. The site with d₀₀₁= 13.55 ± 0.07 Å was not well
13 reproduced for any of these models.
14
15
16
17
18

19 On the other hand, the comparison of the predicted Na-MMT and Co-MMT d₀₀₁
20 shows that the Cobalt incorporation in the MMT lattice produces an expansion of the
21 d₀₀₁ plane, shifting the d₀₀₁ about 3.23 Å, close to that determined experimentally. So,
22 from this correspondence it can be inferred that Co sorption in MMT incorporates the
23 Co atom in the interlayer of the MMT clay, and not as a superficial adsorption, being
24 this fact up to now not discarded.
25
26
27

28 In order to quantitatively evaluate if the Co sorption is favored, total energies
29 obtained from *ab-initio* calculation for MMT system with Na and Co performing using
30 the GIPAW code with and without spin polarization were performed. For the case of
31 Co-MMT, the spin-polarized case was that with lower energy, so all the energy
32 differences are calculated referred to the spin-polarized case. We considered the
33 formation energy and the bond energy as:
34
35
36
37

$$\Delta E_{X-MMT}^{form} = E_{tal} - (E_{layer} + 2E_X + nE_{H_2O}) \quad (1)$$

$$\Delta E_{X-MMT}^{bond} = E_{total} - (E_{layer} + E_{interlayer}) \quad (2)$$

38
39
40
41
42
43 Where X stands for Na or Co. For the calculation of the total energy E_X , there
44 were computed the corresponding to the bulk compounds, divided by the number of
45 atoms of the structure. For the E_{H_2O} term, the total energy of the free molecule was
46 calculated, and n represents de number of molecules for each case. For the E_{layer}
47 term, it was computed the total energy of the crystalline structure but without the atoms
48 of the interlayer (Figure 3), and *vice versa* for the $E_{interlayer}$ term. In MMT the layers
49 are negatively charged, so the presence of the cation in the interlayer stabilizes the
50 structure. Then, the E^{bond} can give information of the charge stability. The resulting
51 energies using Eqs. (1) and (2) are shown in Table II. It can be seen that the Co
52
53
54
55
56
57
58
59
60

1
2
3 incorporation related to the formation of the Co-MMT phase is favored with respect to
4 the Na incorporation in the Na-MMT system, and the energy related with the charge
5 stability remains the same. So, it can be concluded that Co-Na exchange is
6 energetically favored.
7
8
9

10 **b- Hyperfine characterization**

11
12
13 As it is known the external magnetic field used in NMR experiments at probe
14 sites are normally shielded by a shielding coefficient which depends on the local
15 environment (σ_{sample}). The determined experimental chemical shift is related with the
16 isotropic shielding σ_{sample} and could be compared with calculated ones taking into
17 account the standard expression:
18
19
20
21

$$22 \quad \delta_{\text{chem}} = \sigma_{\text{Ref}} - \sigma_{\text{sample}} \quad (3)$$

23
24
25 Starting from the optimized cell parameter, the NMR parameters were
26 evaluated on each atomic site using the GIPAW code. The obtained magnetic
27 shielding, the mayor component of the electric field gradient tensor represented in the
28 local principal axis V_{zz} and the corresponding asymmetry parameter $\eta = \frac{V_{xx} - V_{yy}}{V_{zz}}$ are
29 summarized in Table III. Regarding the O atoms, it can be seen in Fig. 1 that the SiO_4
30 tetrahedra are oriented in such a way that each tetrahedron has one basal plane
31 approximately parallel to the interlayer, so, these are the oxygen atoms capable to
32 bond with the $\text{Na/Co} + n\text{H}_2\text{O}$ units, although just one or two of them will effectively act
33 as bonding atom. On the other hand, on the opposite vertex of the tetrahedron the
34 corresponding O atom is shared with a (Al/MgO_6) octahedron, thus acting as a bridge
35 between these units. Moreover, the O atoms of the (Al/MgO_6) units that are not shared
36 with any SiO_4 units form $(\text{OH})^-$ groups. Finally, there are O atoms that belong to the
37 H_2O units, and only bind with the H and the Na/Co. In Table III it can be seen that O
38 atoms were correspondingly divided in three groups, named O_{basal} , O_{apical} and O_{OH} ,
39 corresponding to the first three groups respectively. The results for the last group are
40 not shown. As it is known, the hyperfine parameters (HP) are highly sensitive to local
41 distortions due to their dependence on the charge density near and at the nuclei
42 positions. So, in perfect symmetric tetrahedron or octahedron units it should be
43 expected similar values in the HP of the constituent O atoms, and on the contrary,
44 differences in the HP are signals of strong local deformations of the units. For example,
45 in Table III it can be seen that, for the NaM1 structure, the V_{zz} of the O_{basal} are mainly in
46
47
48

55
56
57
58
59
60

1
2
3 the 9-10 $\cdot 10^{21}$ V/m² range, except for O1, O4 and O11. In Figure 4a it can be seen in
4 correspondence that O1 form the chemical bond with the Na+4H₂O unit, resulting the
5 corresponding tetrahedron strongly deformed. In the upper part of the interlayer, O4
6 displaces from the basal plane towards the interlayer in a sort of O-H-O bridge, thus
7 also producing a strong deformation of the tetrahedron. Finally, O11 is shared between
8 the basal plane of the corresponding tetrahedron and a free H. In correspondence, the
9 V_{zz} for the O_{apical} are mainly in the 4.6-5.6 $\cdot 10^{21}$ V/m², except for O16 and O18, which
10 are the apical oxygen atoms of the deformed SiO₄ tetrahedra that share the basal O4.
11 A similar reasoning can be done for the HP parameters at the Si atoms in these
12 structures: the SiO₄ tetrahedrons of Si3 and Si5 are geometrically similar, as those of
13 Si4 and Si6, then the corresponding V_{zz} and η values are near the same. In the lower
14 plane of tetrahedra in Fig. 4a it can be seen that they are all geometrically different due
15 to proximity of the (Na+4H₂O) unit and the different bonding, consequently the HP of
16 the corresponding Si atoms spread over a range of values. Interestingly, it should be
17 noted that V_{zz} and η have much more sensitivity to the mentioned deformations than
18 the σ_{sample} for the case of Si, and the opposite occurs for the O. For the case of the Al
19 and Mg atoms, it should be noted that σ_{sample} has nearly constant values around 545
20 ppm for both type of atoms, whereas the corresponding V_{zz} and η have very different
21 values between atoms in same the group.

22
23 In the case of the oxygen atoms in the O_{basal} group of the NaM2, O1, O3 and O4
24 are the atoms that show out of range values. In Fig. 4b it can be seen that O1 and O3
25 are the bonding atoms between the (SiO₄) layer and the (Na+2H₂O) units, thus
26 producing an elongation in the tetrahedral faces. O4 stands for an O-H-O bridge as in
27 the previous case. In this case the similar deformed tetrahedra are those containing Si1
28 and Si7, and the pair Si2-Si8. Thus the corresponding apical oxygen O19-O13 and
29 O20-O14 have very similar HP. Other pairs of similar O_{apical} bonding can be observed
30 from Table V.

31
32 In Fig. 5 it can be observed the relaxed cell of the CoM1. As a difference with
33 the NaM1 and NaM2 cases, it can be observed that the elongation of the cell in the c-
34 direction causes the interlayer (Co + 6H₂O) units to be displaced further away from the
35 O_{basal} atoms than in the previous cases, i.e., the enlargement is practically all contained
36 in the interlayer spacing. As a result, in this structure do not appear Co-O_{basal} chemical
37 bonds similar to the Na-O1 in the NaM1 or the Na-O1 + Na-O3 of the NaM2.
38 Nevertheless, O4 and O3 are displaced towards the interlayer, thus producing strongly
39 deformed tetrahedra. This fact is reflected in their corresponding HPs which are out of
40 the mean values also for V_{zz} and σ_{sample} (Table III). Regarding the (Co + 6H₂O) units, it
41 appears an unexpected behavior after relaxing the atomic positions. It can be observed
42

that the corresponding units to Co1 and Co2 are different. Co1 maintains a nearly regular octahedron of 6 H₂O molecules, but Co2 is located in such a way that it is closer to one of the water molecules originally from Co1 (W1 in Fig. 5) than to one water molecule from its original unit (W2). So, this forms a strongly deformed octahedron, linked to the corresponding Co1 with a Co1-O-Co2 bridged structure, and releasing a water molecule.

c- Comparison with experimental results

From the ab-initio results the chemical shift for each probe site of the MMT can be determined. On one hand, for the use of Eq. 3 the corresponding σ_{Ref} values must be provided, nevertheless a search in the literature does not shield unique values. On the other hand, other authors use an empirical model in which there is linear relation between the chemical shift δ_{chem} and the isotropic shielding σ_{sample} in which the coefficients for the linearization are obtained from a linear regression from measurements on many different compounds:

$$\delta_{\text{chem}}(\text{ppm}) = A * \sigma_{\text{sample}} + B \quad (4)$$

Also for this approach, after a selected search within this model at least two pair of values can be found for the linear coefficients A and B. In Table IV there are shown the data collected from the literature.

Unfortunately, up to our knowledge there are no reports for measurements using the ¹⁷O isotope as probe atoms for this type of MMTs, nor NMR experiments reported on Co-MMT. Thus, for the comparison with the experiment we will restrict to the HP on Al, Mg, Si and Na for the NaM1 and NaM2 structures. In Table V there are shown the HP obtained from the literature from NMR experiments on Na-MMT. From the predicted HP (Table III) we calculated the chemical shift for each one of these atoms, using Eq. 3 and Eq. 4. Thus we obtained a set of values that depend on the model and the experimental σ_{Ref} , and the A and B set of parameters. For σ_{sample} for the different Al, Si, Na and Mg atoms we used those obtained from the corresponding average of the predicted values from Table III. For the determination of V_{zz} from NMR data we used:

$$C_Q = \frac{V_{\text{zz}} Q e}{h} \quad (5)$$

$$P_Q = C_Q \sqrt{1 + \frac{\eta^2}{3}} \quad (6)$$

1
2
3 by means of the corresponding quadrupolar moment Q after averaging the obtained
4 moduli of the V_{zz} for the same type atoms.

5
6 As it can be seen, the calculated ^{29}Si chemical shift is in good agreement with
7 the reported chemical shift in the literature. Regarding ^{23}Na , the comparison of the
8 calculated δ_{chem} with the experimental one becomes difficult due to the strong
9 dependence on the A and B empirical parameters selection. Specially, the B parameter
10 presents strong differences between the data from Ref[64] and Ref[37], and this
11 difference particularly affects the results for chemical shifts near zero, as in this case.
12 On the other hand, the V_{zz} obtained values are not far from the experimental data. For
13 Mg, the calculated δ_{chem} using Ref[37] resulted higher than that observed in Ref[26].
14 Also, the V_{zz} are higher for both models NaM1 and NaM2. On the contrary, the
15 obtained η are in good agreement with the experiment. For ^{27}Al it can be seen that V_{zz}
16 are in good agreement with the range extracted from the work of Takahashi et al. (the
17 range comes from the indetermination η , taking the extreme values 0 and 1) for both
18 NaM1 and NaM2. Nevertheless it must be observed that the comparison is performed
19 with the mean value of the V_{zz} module for all the Al sites. While for NaM2 all the Al sites
20 have uniform V_{zz} values, the corresponding values in NaM1 present strong fluctuations.
21 These fluctuations are not reflected in the individual σ_{sample} , nonetheless the obtained
22 chemical shifts resulted above the experimental result using Eq. 3 or Eq. 4.

34 6- Conclusions

35
36
37 Cobalt sorption on natural Na-MMT was experimentally studied. From the
38 results of the XRD spectra and analysis of the solid and residual liquid phase it was
39 concluded that Co^{2+} was introduced in the sample and as a result the layered structure
40 was strongly enlarged in the direction perpendicular to the interlayer.
41

42
43 DFT calculations can be an important tool to contribute to resolve issues
44 relating to the structure of natural and synthetic layered materials. This theory was
45 successfully used to reproduce the changes introduced in MMT structure upon
46 substitution of Na by Co as it was observed. Regarding the total energy values, *ab*
47 *initio* calculation predicts that the replacement, though sorption, of Na by Co in Na-
48 MMT is energetically favorable. Three different models with different hydration/Na-
49 concertation state were tested to reproduce the Na-MMT samples and one for the
50 obtained Co-MMT. Within these models of Na-MMT, two of them with 4 H_2O and one or
51 two Na atoms give d_{001} parameters compatible with the natural sample, whereas the
52 third model with 2 Na atoms and 8 H_2O have been discarded due to the high d_{001}
53

1
2
3 values obtained at equilibrium. The Co-MMT model with 2 Co atoms and 6 H₂O
4 resulted in a d_{001} compatible with that obtained experimentally in this work.
5

6 In this work we observed that the substitution of the Na-n(H₂O) by Co-m(H₂O)
7 produces not only an enlargement of the cell, but also a re-organization of some of the
8 O atoms of the SiO₄ tetrahedrons that affect the geometry of the sheets, thus changing
9 their properties.
10

11 The hyperfine parameters on all models were calculated giving a good
12 approach to the experimentally determined by NMR. The equilibrium configuration
13 together with the tetrahedra and octahedral geometry of the (SiO₄) and (Al/MgO₆) units
14 were discussed and related with the corresponding hyperfine parameters.

Fig. 1: MMT structure. Si atoms (blue) form tetrahedrons with four bonding O (red) in SiO_4 units. Mg and Al atoms (light blue and orange respectively) form octahedrons with the six bonding O in $(\text{Mg/Al})\text{O}_6$ units. H atoms are light-grey. In the interlayer, the Na atoms (yellow) are surrounded by four H_2O molecules in this example case.

Fig. 2: Partial X-ray diffractions for natural MMT before (dark yellow) and after (red) Co^{2+} sorption process. The simulated XRD lines obtained from fits with Voight functions are also included

Fig. 3: Schematic division of the unit cell of MMT. The interlayer blocks consist of the ((Al/Mg)O₆) and the (SiO₄) octahedron/tetrahedron units, while in the interlayer there are the Na or Co together with their surrounding H₂O.

Fig. 4: NaM1 (a) and NaM2 (b) structures after atomic position and cell parameters relaxation. Some Na, Si and O atoms are numbered in correlation with the text.

Fig. 5: CoM1 structure after atomic position and cell parameters relaxation. Some Co and O atoms are numbered in correlation with the text

Table I: Lattice parameters, d_{001} [Å] and angles [°] obtained from the structure relaxation for the different configurations. (*) data from this work.
