11

12 The evolutionary history of the South American anteaters, Vermilingua, is incompletely

13 known as consequence of the fragmentary and geographically biased nature of the fossil

14 record of this group. The only record of a nominal extinct species for northern South

15 America is *Neotamandua borealis*, from the Middle Miocene of La Venta area,

16 southwestern Colombia (Hirschfeld 1976). A new genus and species of myrmecophagid for

17 La Venta is described here from a new partial skull. Additionally, the taxonomic status of

18 the genus to which was referred the co-occurrent species of Gen. et sp. nov., i.e.

19 *Neotamandua*, is revised. The morphological and taxonomic analyses of these taxa indicate

20 that Gen. et sp. nov. may be related to *Tamandua* and that the justification of the generic

21 assignments of the referred species to *Neotamandua* is weak, with high probability of

22   reassigning some of them to a new genus. Two species previously referred to *Neotamandua*

23   (*N. magna* and *N.? australis*) were designated as *species inquirendae* and new diagnostic

24   information for the redefined genus and its type species, *N. conspicua*, is provided.

25   Together, these results suggest that the diversification of Myrmecophagidae was

26   taxonomically and biogeographically more complex than that what has been proposed so

27   far. Considering the new evidence, it is proposed a synthetic model on the diversification of

28   these xenartrans during the late Cenozoic based on the probable relationship between their

29   intrinsic ecological constraints and some major abiotic changes in the Americas.

30   **Key words:** Vermilingua, Myrmecophagidae, diversification, *Neotamandua*, La Venta

31   area, Neogene.

32

Introduction

34   The anteaters of the suborder Vermilingua are part of Xenarthra, one of the more inclusive

35   clades in the evolutionary tree of the placental mammals (Eutheria) and a characteristic

36   group in the land mammal assemblages of the middle-late Cenozoic of the Americas

37   (McDonald et al. 2008; Foley et al. 2016; Halliday et al. 2016; Feijoo & Parada 2017).

38   Within Xenarthra, Vermilingua belongs to Pilosa, a clade that also includes the sloths, i.e.

39   Tardigrada. Today, Vemilingua comprises the genera *Cyclopes* (pygmy anteaters),

40   *Tamandua* (collared anteaters) and *Myrmecophaga* (giant anteaters). These genera groups

41   ten extant species, the most of them (seven) belonging to *Cyclopes*, according to the most

42   recent exhaustive taxonomic revision (Miranda et al. 2017). The classic phylogenetic

43   hypothesis reunites *Tamandua* and *Myrmecophaga* in the family Myrmecophagidae, while

44 *Cyclopes* is located in a basal position with respect to Myrmecophagidae as the only recent

45 form of the family Cyclopedidae (Engelmann 1985). With the connotation of a superior

46 taxonomic hierarchy (i.e. at the family level; Barros et al. 2008; Gibb et al. 2015) by an

47 early evolutionary divergence (Hirschfeld 1976; Delsuc et al. 2001; Gibb et al. 2016) and in

48 acknowledgment of a more extended use in the scientific literature, the names

49 Myrmecophagidae and Cyclopedidae are used here, instead of Myrmecophaginae and

50 Cyclopinae *sensu* Gaudin & Branham (1998), respectively. However, the taxonomic

51 content of Myrmecophaginae and Cyclopinae, including extinct forms, is considered as

52 transferable to their counterparties (McDonald et al. 2008).

53 The living anteaters, whose mean body mass ranges from ~0.4 and 30 kilograms (Gaudin et

54 al. 2018), are highly, morphologically specialized mammals by exhibiting remarkable

55 skeleton and soft-anatomy modifications, which are closely linked to their

56 myrmecophagous diets, i.e. diets consisting of at least 90% of ants/termites (Redford 1987;

57 McDonald et al. 2008). Many of these adaptations, anatomically located in the skull and

58 jaws, are associated between them in several ways by being part of the architecture of an

59 integrated functional system of food apprehension and ingestion. Among these features, the

60 following are some of the most noteworthy: rostral elongation and narrowing, basicranial-

61 basifacial axis curvature, complete loss of teeth, gracile jaw, reduction of the adductor jaw

62 muscles, unfused jaw symphysis and protrusible long tongue (Reiss 2001; Gaudin &

63 McDonald 2008; McDonald et al. 2008). Several of these morphological specializations are

64 convergent with those described for other myrmecophagous mammals such as the

65 pangolins (Pholidota) and the aardvarks (Tubulidentata), so it is not surprising that early

66 systematic researchers erroneously proposed close common ancestry of Vermilingua with

67   these Old world groups from their superficial similarities (e.g. Engelmann 1978; Norman &

68   Ashley 1994).

69   Despite their unique biology and ecology, at least in the context of the land mammals of the

70   Americas, the evolutionary history of the anteaters is largely obscured by their poor,

71   fragmentary and geographically biased fossil record (Hirschfeld 1976; Gaudin & Branham

72   1998; McDonald et al. 2008). Generally, five valid genera and nine species are recognized

73   in the fossil record of Vermilingua, of which two genera and two species have extant

74   representatives, i.e. *Myrmecophaga tridactyla* and *Tamandua tetradactyla*.

75   Myrmecophagidae groups nearly all these fossil taxa (only one genus and one species for

76   Cyclopedidae) in a general biochron beginning c. 18 million years before present, most of

77   them distributed throughout the Neogene (McDonald et al. 2008). But while the record of

78   this family for the latter period is taxonomically more diverse than that for the Quaternary,

79   it also poses more difficulties in the systematic framework of the implicated taxa. The

80   oldest member of Myrmecophagidae is *Protamandua rothi*, from the late Early Miocene of

81   the Santa Cruz Province, southern Argentina (Ameghino 1904). This species has been well

82   validated from a pair of incomplete skulls and several postcranial bones, but the validity of

83   other co-occurrent putative vermilinguan (myrmecophagid?) taxa is, at least, questionable

84   (Hirschfeld 1976; McDonald et al. 2008). For the early Middle Miocene has been reported

85   a myrmecophagid doubtfully assigned to *Neotamandua*, and yet used to create a new

86   species from isolated humeral remains (*N.? australis*; Scillato-Yané & Carlini 1998). In the

87   latter genus was also allocated, with some uncertainty, postcranial material of a middle-to-

88   large sized anteater recorded in the late Middle Miocene of La Venta area, southwestern

89   Colombia, whose description includes the only nominal extinct species for northern South

90   America, i.e. *N. borealis* (Hirschfeld 1976). *Neotamandua* chronologically extends to the

91   Late Miocene and Early Pliocene with the species *N. magna* (Ameghino 1919), *N.*

92   *greslebini* (Kraglievich 1940) and *N. conspicua* (type species; Rovereto 1914), all of them

93   from northwestern Argentina (provinces of Catamarca and Tucumán). This genus is

94   typically recognized as morphologically similar (even directly ancestral) to *Myrmecophaga*,

95   although smaller in body size (Hirschfeld 1976; Gaudin & Branham 1998). Considering the

96   very few anatomically correlatable elements in which are based the different species

97   referred to *Neotamandua*, Hirschfeld (1976) and Scillato-Yané & Carlini (1998) have

98   suggested that this genus could be paraphyletic. Furthermore, the latter authors proposed

99   the hypothesis that *Neotamandua* is composed by two distinct evolutionary lineages: one

100   more closely related to *Myrmecophaga* and other one to *Tamandua*. In turn, these two

101   lineages would have diverged in allopatry in South America, in such a way that the

102   geographical origin of *Myrmecophaga* is located in northern South America, while that of

103   *Tamandua* is in southern South America.

104   In this article, we describe the first fossil skull of a myrmecophagid (and vermilinguan)

105   from northern South America. This specimen was collected in the Middle Miocene La

106   Victoria Formation of La Venta area, Colombia. Additionally, in coming to analysis

107   because it is the only nominal taxon reported for the same region and geological unit, the

108   taxonomic status of *Neotamandua* is revised. The results prompt the development of a

109   discussion on a model of diversification for Myrmecophagidae in which new and previous

110   hypothesis about this evolutionary event are synthesized. This contribution is intended to

111   revaluate, expand and integrate biotic and abiotic evidence related to the diversification of

112   this fascinating mammal group, with emphasis on the biogeographic role of tropical, low

113   latitude regions of the Americas.

114

Material and methods

116   The cranial specimen described for the first time here for Colombia (VPPLT 975) comes

117   from a light-brown mudstone layer in the Llano Largo field, around 2 Km northeast of La

118   Victoria town, Municipality of Villavieja, Department of Huila (Fig. 1A-C). Strata of the

119   La Victoria Formation outcrop there, within the palaeontologically relevant area of La

120   Venta. The La Victoria Formation is a geological unit of ~500 meters in thickness which is

121   mainly composed by bioturbated mudstones (Anderson et al. 2016). These sedimentites are

122   interrupted by very continuous, coarse-to-fine grained sandstones with crossbedding and

123   erosive bases. According to the lithostratigraphic scheme of Guerrero (1997; Fig. 1D), the

124   new skull is from a level stratigraphically close (<20 m) and below the Chunchullo

125   sandstone beds, i.e. the lower part of the La Victoria Formation. This corresponds to the

126   unit referred as "Unit between the Cerro Gordo and Chunchullo sandstone beds". As

127   described by the same author, this unit, whose thickness ranges from ~80 to 160 m, is

128   predominantly composed of mudstones and some interlayers of sandstones. This

129   sedimentary body bears abundant plutonic and volcanic fragments from the lower Jurassic

130   basement of the Honda Group (Saldaña Formation), as well as clasts of volcanic rocks

131   formed in the magmatic arc of the Cordillera Central of Colombia during the Middle

132   Miocene (Anderson et al. 2016).

133 The general palaeoenvironment inferred for the La Victoria Formation is a meandering

134 fluvial system (except for the Cerbatana conglomerate, associated to an anastomosed

135 system) with significant soil development in flood plain zones (Guerrero 1997). The ages

136 calculated by Guerrero (1997) and Flynn et al. (1997) using magnetic polarity stratigraphy

137 and geochronology indicate sedimentary deposition during the interval 13.8□12.5 million

138 years ago (mya). These results have recently been reinforced by the U-Pb geochronology of

139 detrital zircons recovered in this formation (Anderson et al. 2016). The age range obtained

140 is 14.4 ± 1.9 □ 13.2 ± 1.3 mya. This interval coincides approximately with the early

141 Serravalian, sub-stage of the Middle Miocene [Insert Fig. 1 here].

142 Cranial measurements, with some nomenclatural modifications, are based on those of

143 Hossotani et al. (2017) (Fig. 2; see Anatomical Abbreviations). All these measurements are

144 in millimetres (mm). The description of the new skull of La Venta includes a rough body

145 mass estimation of the respective individual from a traditional allometric approach. All

146 these data and analyses are compiled in the Supplementary material (Appendices S1 and

147 S3). For the taxonomic analysis of the genus *Neotamandua* were revised the justifications

148 of generic allocations for the referred species (at least doubtfully) in all the relevant

149 scientific literature. These species are: *Neotamandua conspicua* Rovereto 1914 (type

150 species); *Neotamandua magna* Ameghino 1919; *Neotamandua greslebini* Kraglievich

151 1940; *Neotamandua borealis* Hirschfeld 1976; *Neotamandua*? *australis* Scillato-Yané &

152 Carlini 1998. Additionally, some observations were made on the holotypes of *N. conspicua*

153 (MACN 8097) and *N. borealis* (UCMP 39847) to reexamine the described characteristics

154 for these species in the original publications (Rovereto 1914 and Hirschfeld 1976,

155 respectively). The conceptual model of Plotcnick & Warner (2006) to recognize taxonomic

156   wastebaskets was applied to *Neotamandua*. From the foregoing and the designation of the

157   specimen FMNH P14419 as epitype of *N. conspicua*, it was proposed a diagnosis for

158   *Neotamandua*. See a list of all the studied fossil specimens in the Appendix S1 of the

159   Supplementary material [Insert Fig. 2 here].

160   On other hand, considering that Hirschfeld (1976), in her description of *N. borealis*, did not

161   include morphological comparisons from postcranial bones of this species and homologous

162   elements of the species referred to *Neotamandua* for southern South America, we

163   performed this task and a preliminary character distribution analysis from postcrania of

164   these taxa to explore the hypothesis that they are closely related. Forcibly, *N. magna* and

165   *N.? australis* are excluded from the comparisons since they do not have osteological

166   elements correlated with those of *N. borealis* (or any other species referred to

167   *Neotamandua*). Additionally, as a result of loss of its holotype (McDonald et al. 2008),

168   comparisons with *N. greslebini* are based exclusively on the non-illustrated description by

169   Kraglievich (1940). Other comparisons include postcranium collected by Juan Méndez in

170   1911 in the upper Miocene of the Andalhuala locality, Catamarca Province, Argentina. This

171   material was assigned to *Neotamandua* (*Neotamandua* sp.) without a reference publication.

172   McDonald et al. (2008) manifested doubt about this taxonomic assignment

173   (*Neotamandua*?), but these authors simultaneously speculated that it might be the lost

174   holotype of *N. greslebini*.

175   Following to McKenna & Bell (1997), the genus *Nunezia* is considered a junior synonym

176   of *Myrmecophaga*. Myological inferences are based on Hirschfeld (1976) and Gambaryan

177   et al. (2009).

(Fig. 3)

</div>

205

206

207 **Etymology.** [intentionally in blank]

208 **Holotype.** VPPLT 975, anterior portion of a skull, without jugals nor premaxillae.

209 **Diagnosis.** Middle sized myrmecophagid, slightly smaller than *Tamandua* and even more

210 than *Neotamandua*. It can be differentiated from other genera/species of anteaters by the

211 following combination of cranial features: relatively width rostrum, similar to *Tamandua*;

212 narrow and strongly tapered nasals toward their anterior end; anteroposterior length of the

213 pre-orbital section of frontals equal to more than two thirds of the anteroposterior length of

214 nasals; jugals inserted from the same level of the most anterior border of the lacrimal;

215 anterior portion of the orbit more laterally extended in the superior wall in the inferior one,

216 without forming a conspicuous dome as in *Neotamandua conspicua*.

217 **Comparative description of the holotype of Gen. et sp. nov.** The specimen VPPLT 975

218 consists of a partial skull that preserves nearly all the anatomical elements from the anterior

219 section of the frontals (at the mid anteroposterior level of the orbit) to the anterior end of

220 the rostrum. See cranial measurements taken for this new taxon and other myrmecophagids

221   in the Table 1. The estimated body mass for this individual is around 3.9 Kg (Appendix S3

222   of the Supplementary material). As consequence of the preservation, some sutures are

223   distinguishable in dorsal and lateral views, but virtually no suture is clearly detectable in

224   ventral view. The rostrum is proportionally shorter and more robust than those in

225   *Myrmecophaga* and *N. conspicua* (see below), but less than in *Tamandua*. In dorsal view, it

226   is very similar to the skull of *Tamandua*, with at least four characteristics remarkably

227   different with respect this extant genus: (1) lower rostrum; (2) rostrum more regularly

228   tapered; (3) narrower and more anteriorly tapered nasals; (4) pre-orbital section of the

229   frontals more anteroposteriorly elongated. In dorsal view, the rostrum shows a slight bulge

230   in its middle part, similar to that in *Tamandua* and *Myrmecophaga*. However, in VPPLT

231   975 this bulge is even subtler than in the living myrmecophagids. Apparently, the nasals are

232   shorter than frontals and are poorly exposed in lateral view. The jugals are absent by

233   preservation, but it is possible to recognize their insertion location. This is more anterior

234   than in *Myrmecophaga*, but more posterior than in *Tamandua*. Associated to the insertion

235   of the jugal, there is a reduced posterolateral process of the maxilla in comparison with that

236   of *Myrmecophaga*, similar in *Tamandua*. The right side of the skull preserves better the

237   lacrimal zone, but it is simultaneously more deformed around the fronto-maxillary suture

238   than in the left side. The lacrimal is longer in its anteroposterior axis than in that

239   dorsoventral. The same bone is proportionally smaller than in *Tamandua* and even more

240   than in *N. conspicua*. It has a triangular outline (at least anteriorly), similar to

241   *Myrmecophaga* and unlike *Tamandua* (irregularly rounded, ovated, or, infrequently, sub-

242   triangular lacrimal). The maxilla is not part of the orbit. The superior wall of the orbit is

243   more laterally expanded than the inferior wall, without forming a conspicuous dome as in

244   *N. conspicua*. This is similar to the condition observed in *Myrmecophaga* and differs from

245   that in *Tamandua*, in which the inferior wall is prominent given that it is more laterally

246   expanded. It is not possible to recognize lacrimal nor orbital foramina. In ventral view, the

247   dorsal border of the orbit is regularly concave. The palatines are less laterally extended than

248   in *Tamandua* and apparently there are no palatine "wings" (noticeable lateral expansions of

249   the palatines), unlike *N. conspicua* [Insert Fig. 3 here].

250

Taxonomic reanalysis of the genus *Neotamandua*

251

Taxonomic history and discussion on the taxonomic status of *Neotamandua*

252

253   The genus *Neotamandua* was proposed by Rovereto (1914) from a posterior portion of a

254   skull (MACN 8097), which was collected in upper Miocene-to-Pliocene strata of the

255   Catamarca Province, Argentina. The name *Neotamandua*, literally meaning 'new

256   tamandua', was coined by Rovereto in allusion to the cranial similarity of the type species,

257   *N. conspicua*, with the extant genus *Tamandua*, rather than with *Myrmecophaga*. This

258   detail would be historically paradoxical, as will be shown below. It is important to note that

259   Rovereto did not provide a diagnosis for *Neotamandua*, but he just briefly described the

260   holotype of *N. conspicua*, emphasizing its elongated parietals. However, this feature, more

261   comparable with that in *Myrmecophaga* than that in any other myrmecophagid, was

262   correlated with the anteroposterior length of the parietals in *Tamandua*. A few years after

263   the Rovereto's work, Carlos Ameghino (Ameghino 1919) used a pelvis (MPT 58)

264   recovered in contemporary strata of the Tucuman Province, Argentina, to create a new

265   species, *N. magna*. Despite the taxonomic assignment of this pelvis to *Neotamandua*,

266   Ameghino discussed that, alternatively, this species could belong to other genus of larger

267   body size, as Kraglievich (1940) also held. Formally, *N. magna* has not been reevaluated,

268   but McDonald et al. (2008) suggested that, given that this species was transferred to

269   *Nunezia* by Kraglievich (1934), and *Nunezia* is considered a junior synonym of

270   *Myrmecophaga* (Hirschfeld 1976; McKenna & Bell 1997), then *N. magna* should be

271   included in the latter genus, i.e. *Myrmecophaga magna* comb. nov. (unpublished). Indeed,

272   the morphological differences cited by Ameghino (1919) and Kraglievich (1940) between

273   the pelvis of *N. magna* and that of *M. tridactyla* (e.g. greater width and ventral flattening of

274   the intermediate sacral vertebrae) do not seem sufficient to consider a generic distinction

275   between these species.

276   Two decades later, Kraglievich (1940) proposed a new species from postcranium collected

277   in the upper Miocene of the Catamarca Province. This was initially assigned to *N.*

278   *conspicua*. According to Kraglievich, the then new species, *N. greslebini*, is easily

279   identifiable by its large size, intermediate between those of *N. conspicua* and *N. magna*.

280   Like Rovereto (1914), this author also correlated his generic assignment of *N. greslebini* to

281   *Neotamandua* from the similarity between the fossil specimens of this species and

282   homologous elements of *Tamandua* (Kraglievich, p. 633). The holotype of *N. greslebini* is

283   missing or mixed up with material labelled with generic names of extinct anteaters (i.e.

284   *Neotamandua* and *Palaeomyrmidon*) in the Museo Argentino de Ciencias Naturales

285   (MACN), in Buenos Aires, Argentina (McDonald et al. 2008).

286   Already in the second half of the XX century, a controversy about the possible synonymy

287   between *Neotamandua* and *Myrmecophaga* arose. This means that there was a radical

288   paradigmatic shift in myrmecophagid systematics, from that in early XX century, in which

289   *Neotamandua* was considered closely related to *Tamandua*, to that in late XX century, in

290   which *Neotamandua* was even a serious candidate to be a junior synonym of

291   *Myrmecophaga*. This historical change began with the non-cladistic systematic analysis of

292   Hirschfeld (1976), in which *Neotamandua* was originally proposed as the direct ancestor

293   (anagenetic form) of *Myrmecophaga*. In the same work, Hirschfeld created the first and,

294   until now, only nominal extinct species of Vermilingua and Myrmecophagidae for northern

295   South America, *N. borealis* (Middle Miocene of Colombia). Given the scarcity and

296   fragmentation of the specimens referred to *Neotamandua*, Hirschfeld recognized the need

297   to revise the taxonomic validity of *N. conspicua*, *N. magna* and *N. greslebini*. Indeed, she

298   went beyond and stated that *Neotamandua* species could be representatives of more than

299   one single genus. However, her assignment of *N. borealis* to *Neotamandua* was based

300   primarily on the idea that the fossils she studied are 'considerably more advanced than

301   those known from the Santacruzian [late Early Miocene], closer to the Araucanian [Late

302   Miocene-Pliocene] species and…to the line leading to *Myrmecophaga* than *Tamandua*'

303   (Hirschfeld, p. 421). For this author, many postcranial traits of *N. borealis* are intermediate

304   between *Tamandua* and *Myrmecophaga*. As a questionable methodological aspect, it is

305   important to note that Hirschfeld did not make osteological comparisons with the southern

306   species of *Neotamandua*, only with postcranium of *Protamandua*, *Tamandua* and

307   *Myrmecophaga* (extant species of the two latter genera).

308   In implicit reply to Hirschfeld (1976), Patterson et al. (1992) highlighted the morphological

309   similarities between the unpublished skull FMNH P14419, catalogued as *N. conspicua* in

310   the Field Museum, and the modern skulls of *Myrmecophaga*. For these authors, FMNH

311   P14419 only differs from skulls of the living giant anteater in its smaller size.

312   Consequently, Patterson et al. (1992) suggested synonymize *Neotamandua* and

313   *Myrmecophaga*, with nomenclatural priority for the latter. Nevertheless, Gaudin &

314   Branham (1998) provided (weak) support for the validity of *Neotamandua* through a

315   comprehensive phylogenetic analysis of Vermilingua. Their results indicate that

316   *Neotamandua* is an independent taxon based on two autapomorphies, being one of them

317   ambiguous and the other one unambiguous. The latter is the horizontal inclination of the

318   glenoid. In the only most parsimonious tree recovered by Gaudin & Branham (1998),

319   *Neotamandua* is closely related to *Myrmecophaga*, not *Tamandua*, as opposed to Rovereto

320   (1914) and Kraglievich (1940).

321   Finally, the last species referred, with doubt, to the genus was *N.? australis* (Scillato-Yané

322   & Carlini 1998). The holotype of this species consists only of a humerus (MLP 91-IX-6-5)

323   collected in the lower Middle Miocene of the Río Negro Province, Argentina. Scillato-Yané

324   & Carlini (1998) highlighted some similarities of this material with the humerus of

325   *Tamandua*. They also expressed considerably uncertainty in assigning it to *Neotamandua*,

326   not only by its fragmentary nature, but from the idea of Hirschfeld about the non-natural

327   (i.e. non-monophyletic) status of this genus. Without performing a phylogenetic analysis,

328   these authors proposed a hypothesis that *N. borealis* is closely related to *Myrmecophaga*,

329   while *N. conspicua* and *N.? australis* are closer to *Tamandua*. If this hypothesis is correct,

330   *N. borealis* does not belong to *Neotamandua* as consequence of the application of the

331   nomenclatural priority principle.

332   In summary, multiple historical factors, including the lack of a diagnosis, insufficient

333   number of anatomically correlatable/highly diagnostic postcranial elements and, especially,

334   absence of cranial-postcranial associations, aroused the relatively arbitrary use of

335   *Neotamandua* as a wastebasket taxon, i.e. a residual genus deriving from weak and/or

336   inadequate systematic analysis. According to the conceptual model of Plotnick & Warner

337   (2006), *Neotamandua* has five (from a total of seven) properties of a genus potentially

338   classifiable as wastebasket: (1) it is an old name (i.e. more than one century to the present);

339   (2) it is [relatively] rich in species (five species, i.e. the most speciose extinct genus of

340   Vermilingua); (3) it has a [relatively] high number of occurrences; (4) it has wide temporal

341   and geographical distributions; (5) it [primarily] groups together specimens poorly

342   preserved and/or difficult to identify. To these five properties we may add the lack of a

343   diagnosis, which is related in some way to the property number two of the Plotnick-Warner

344   model, i.e. genera diagnosed from generalized characters, probably plesiomophies or easily

345   recognizable characters.

346   As it was shown, *Neotamandua* has been invoked as a directly ancestral form of

347   *Tamandua*, or, more recently, of *Myrmecophaga*, from its morphological characteristics in

348   common with these two extant genera. But precisely because of this character mosaic, the

349   generic allocation of isolated postcranial remains of myrmecophagids potentially referable

350   to *Neotamandua* should not be reduced or exclusively focused on their comparison with the

351   crown-group, but should also consider the effect of possible homoplasies (e.g. those related

352   to ecological convergences), plesiomorphies and limitations of the fossil record (Plotnick &

353   Warner 2006). In other words, the apparent affinity between isolated postcranial elements

354   of any Neogene anteater and their homologous in *Myrmecophaga* is not enough to make a

355   reliable generic allocation in *Neotamandua*; diagnostic information of the latter genus is

356   needed, preferably autapomorphies, which allow it to be individually identified and not

357   simply as a set of forms similar to *Myrmecophaga*.

358

359   **Comparisons between northern and southern species referred to *Neotamandua***

360   *N. borealis* **and** *N. greslebini.* See the Table 2 for comparison of postcranial measurements

361   between these species.

362   **Radius.** Both *N. borealis* and *N. greslebini* show two longitudinal, parallel radial

363   ridges, of which the lateral ridge is higher and reaches a more distal level than the

364   cranial one. This is similar to the condition observed in *Myrmecophaga* and differs

365   from the distally convergent radial ridges of *Tamandua*. In *N. borealis*, the lateral

366   ridge is even more distally extended than in *N. greslebini,* in such a way that the

367   flanks of this structure contact the lateral border of the styloid process. According to

368   Kraglievich (1940), in the Argentinean species this ridge ends at an intermediate level

369   between the distal end of the cranial ridge and the styloid process.

370   **Tibia.** The type material of *N. borealis* includes a proximal epiphysis and part of the

371   diaphysis of a right tibia. According to Kraglievich (1940), the holotype of *N.*

372   *greslebini* includes two fragments of a tibia, one of them proximal and the other one

373   distal. Both Hirschfeld and Kraglievich claimed greater overall similarity between the

374   tibial fragments of these species and the homologous parts of *Tamandua*, rather than

375   *Myrmecophaga*. This way, the mid-section of the tibias both of *N. borealis* and *N.*

376   *greslebini* is not as strongly triangular as in *Myrmecophaga*. Rather, this bone

377   segment is from gently triangular to sub-rounded in these two species referred to

378   *Neotamandua*, without being rounded as in *Tamandua*.

379   **Astragalus.** Hirschfeld (1976) described the astragalus of *N. borealis* (Fig. 4A-B, 4E-

380   F) as intermediate in morphology and size between those in *Tamandua* and

381   *Myrmecophaga*. In contrast, Kraglievich (1940) stated that the astragalus of *N.*

382   *greslebini* closely resembles that of *Tamandua*. New observations allow to

383   determinate that, in dorsal view, the astragalus of *N. borealis* is more similar to that in

384   *Tamandua* than *Myrmecophaga* as consequence of a lateral side of the trochlea larger

385   than the medial one (trochlear asymmetry). Like *N. greslebini*, the regular concavity

386   in which is inserted the *flexor digitorum fibularis* tendon extends posteroventrally

387   like a well-defined wedge ("pointed shape" in Kraglievich's words) and it contacts

388   the calcaneal facets across the entire width of the latter. In ventral view, the

389   arrangement of the calcaneal facets in *N. borealis* is a kind of 'transition' between

390   that in *Myrmecophaga* and *Tamandua*. In *N. borealis*, the ectal and sustentacular are

391   largely separated by a wide and deep sulcus, but there is an incipient connection. This

392   condition is approximately comparable to that described by Kraglievich (1940) for *N.*

393   *greslebini* and differs from the fully separated calcaneal facets in *Protamandua* and

394   *Tamandua*. In this sense, Kraglievich was not very explicit in pointing out the degree

395   of development of the connection between these facets, but it is inferred that it is not

396   exactly wide as in *Myrmecophaga* when he wrote that '…these calcaneal articulations

397   are, *apparently*, posteriorly fused…' (italics are ours; Kraglievich, p. 635).

398   **Calcaneum.** Like *N. greslebini*, *N. borealis* has a narrow fibular calcaneal facet,

399   which is located laterally and in a slightly different plane with respect to that of the

400   ectal facet (Fig. 4C-D, 4G-H). In both of the former species, the *sustentaculum* is less

401   medially projected than in *Myrmecophaga*. They also show an accessory facet in the

402   anterior end of the calcaneum that articulates with the astragalar head, similarly to

403   *Tamandua*. In all the aforementioned taxa, this facet is closer (even in contact) to the

404   cuboid facet. In *N. borealis* and *N. greslebini*, the cuboid facet is transversely ovate

405   and concave. A unique feature in common for them is the presence of a short

406   tendinous groove (shorter than in *Myrmecophaga*) and strongly concave (Fig. 4H). It

407   is the continuation of the longitudinal and conspicuous ridge that runs the calcaneum

408   in its lateral side. The latter separates tendons of the *fibularis longus* and *accesorius*

409   muscles (Hirschfeld 1976; Gambaryan et al. 2009). In *N. borealis*, this ridge is more

410   conspicuous than in *Tamandua* and less than in *Myrmecophaga* [Insert Fig. 4 here].

411

412   **N. borealis** and **Neotamandua sp.** See the Table 3 for comparison of postcranial

413 measurements between these species.

414   **Radius.** The distal epiphysis of the radius in *Neotamandua* sp. (MACN 2408) is more

415   massive than that in *N. borealis*. In the latter species, the distal end of the radius is

416   relatively stylized, like *Tamandua*. However, the morphologies of *N. borealis* and

417   *Neotamandua* sp. are more comparable between them. In distal view, the styloid

418   process of these species is more elongated and posteriorly oriented than in

419   *Tamandua*. In the latter extant genus, the transverse axis (longer axis) of the facet for

420   distal articulation is forming an angle close to 45° with respect to the plane of the

421   anterior side of the radius, while this axis is nearly parallel with respect that plane in

422   *N. borealis* and *Neotamandua* sp. This difference gives to the distal radius of the

423   compared *Neotamandua* species a non-rotated appearance, unlike the same epiphysis

424   in *Tamandua*. In anterior view, the distal articulation facet of *N. borealis* and

425   *Neotamandua* sp. is visible in wedge shape pointing towards the medial border.

426   Additionally, in the same view, this facet exhibits comparable exposures in both of

427   the latter species, considerably more than in *Tamandua*. The posterior side of the

428   distal epiphysis is from flat to slightly concave in *N. borealis* and *Neotamandua* sp.,

429   unlike the convex posterior side in *N. greslebini* (this observation could suggest that

430   the material of *Neotamandua* sp. is not the holotype of *N. greslebini*, as speculated by

431   McDonald et al. 2008) and *Tamandua*. The distal extension of the lateral ridge in *N.*

432   *borealis* and *Neotamandua* sp. is similar.

433   **Astragalus.** The astragalus of *Neotamandua* sp. (MACN 2406) is only represented

434   by the astragalar body. The medial trochlea is smaller than the lateral trochlea, but

435   this asymmetry is less than in *N. borealis*. In addition, these sections of the trochlea

436   are proportionally less separated in the latter species than in *Neotamandua* sp.

437   **Calcaneum.** The calcaneum is fragmentary in *Neotamandua* sp. (MACN 2411). As

438   in the case of the astragalus, the preserved portion is the bone body. The ectal facet is

439   sub-triangular in shape in *Neotamandua* sp., while it is approximately sub-oval in *N.*

440   *borealis*. The sustentacular facet is more medially extended in the latter species than

441   in *Neotamandua* sp. In both species, the cuboid facet is partially visible in dorsal

442   view, particularly in *Neotamandua* sp. In the same view, the lateral ridge is slightly

443   exposed in *N. borealis*, but not so in *Neotamandua* sp.

444   **Discussion.** The former comparisons allow to recognize a few morphological similarities

445   and differences between homologous postcranial elements of *N. borealis*, *N. greslebini* and

446   *Neotamandua* sp. It is considered that some similarities in these species are potentially

447   diagnostic at the genus level, namely the sub-rounded to gently triangular shape of the tibial

448   mid-section; ectal and sustentacular facets incipiently connected in the astragalus; and a

449   short tendinous groove in the lateral side of the calcaneum (Table 4). These similarities

450   seem to provide support to the hypothesis that these northern and southern South American

451   species referred to *Neotamandua* are closely related and, consequently, that they are

452   correctly included in the same genus. Alternatively, these common features could be

453   symplesiomorphies of a hypothetical lineage of myrmecophagids more late diverging than

454   *Protamandua* and apparently closer to *Myrmecophaga* than *Tamandua*. Provisionally, from

455   the analysis presented, it is proposed to circumscribe the genus *Neotamandua* to the

456   nominal species *N. conspicua* (type species), *N. greslebini* and *N. borealis*. Since *N. magna*

457   and *N.? australis* are doubtfully assigned to *Neotamandua* or its allocation in this genus has

458   been seriously questioned (McDonald et al. 2008; this work), they are considered *species*

459   *inquirendae*, following the International Code of Zoological Nomenclature (Ride et al.

460   1999). To denote the questionable generic allocation of *N. magna* is suggested the use of

461   inverted commas, i.e. '*N.*' *magna*. The material referred to *Neotamandua* sp. seems

462   correctly referred to this genus, but it should be further tested. It is possible that these

463   specimens correspond to a new species.

464   The diagnosis for *Neotamandua* proposed below is largely based on the designation of the

465   specimen FMNH P14419 as epitype for the type species, *N. conspicua*, after considering

466   the fragmentary nature of the holotype of this taxon (MACN 8097; Rovereto 1914), and,

467   consequently, its ambiguity or lack of some taxonomically relevant features, particularly in

468   the rostrum. In addition, the potentially diagnostic postcranial features for *Neotamandua*

469   that has been identified above are also incorporated in the new diagnosis until cranial-

470   postcranial associations are found and studied.

471

472   *Neotamandua* Rovereto, 1914

473   *LSID.* urn:lsid:zoobank.org:act:4EC0ABE1-C013-4113-9956-5DBD6E79FCEA

474   **Type species.** *N. conspicua* Rovereto, 1914.

475   **Other referred species.** *N. greslebini* Kraglievich 1940; *N. borealis* Hirschfeld 1976.

476   **Related *species inquirendae*.** 'N.' *magna* Ameghino 1919 (*Myrmecophaga magna* new

477   combination? See McDonald et al. 2008); *N.? australis* Scillato-Yané & Carlini 1998.

478   **Diagnosis.** Middle-to-large sized myrmecophagid, larger than *Tamandua* but smaller than

479   *Myrmecophaga*. It can be differentiated from other vermilinguans by the following

480   combination of characteristics: in dorsal view, rostrum strongly tapered towards its anterior

481   end (more than in any other myrmecophagid), with a regular transition in width from the

482   anterior portion of frontals to the anterior end of nasals; reduced lacrimal which is not part

483   of the orbit; jugal inserted in posteroventral position with respect to the lacrimal and

484   slightly projected in posterodorsal direction; frontal forming a dorsal dome at the orbit

485   level; hard palate well extended towards the posterior end of the skull, close to the ventral

486   border of the occipital condyles; squamosal (= posterior) zygomatic process dorsally

487   inclined; presence of palatine "wings"; horizontal inclination of the glenoid (Gaudin &

488   Branham 1998); sub-oval to gently triangular shape of the tibial mid-section; ectal and

489   sustentacular facets incipiently connected in the astragalus; short tendinous groove in the

490   lateral side of the calcaneum.

491

492   ***Neotamandua conspicua* Rovereto, 1914**

493   (Fig. 5)

494   *LSID.* urn:lsid:zoobank.org:act:C4DC62D5-6470-4A04-B152-D42ED3BA332C

495   **Holotype.** MACN 8097, posterior portion of a skull.

496   **Epitype.** FMNH P14419, nearly complete skull but with fractured rostrum and partially

497   eroded frontals and parietals.

498   **Geographical and stratigraphic provenance.** MACN 8097 is from an indeterminate

499   locality in the Santa María Valley, Catamarca Province, Argentina (Rovereto 1914).

500   Probably Andalhuala Formation. Upper Miocene (McDonald et al. 2008; Bonini 2014;

501   Esteban et al. 2014).

502   FMNH P 14419 is from the Corral Quemado area, Catamarca Province, Argentina. Corral

503   Quemado Formation. Lower Pliocene (Bonini 2014; Esteban et al. 2014). This specimen

504   was collected by Robert Thorne and Felipe Méndez during the Second Captain Marshall

505   Field Palaeontological Expedition, which was led by Elmer S. Riggs and developed in

506   Argentina and Bolivia in 1926□1927 (Simpson, pers. comm.; Riggs 1928). In the Field

507   Museum, where it is deposited, has been catalogued as *N. conspicua*. No known reference

508   publication exists as support for the taxonomic assignation to this species, except in Gaudin

509   & Branham (1998) and, now, in this work from direct comparison with the holotype.

510   **Diagnosis.** See the diagnosis for *Neotamandua* above. The postcranial diagnostic features

511   included there do not belong to material known for this species.

512   **Comparative description of the epitype.** The skull FMNH P14419 is anteroposteriorly

513   elongated, with a general architecture more similar to that in *Myrmecophaga* than

514   *Tamandua*. The cranial measurements taken for this specimen are shown in the Table 1. In

515   dorsal view, both the rostrum, in general, as well as the nasals, in particular, are anteriorly

516   tapered. The pre-orbital section of the frontals is proportionally less elongated than in

517   *Myrmecophaga*. The lacrimal has a sub-triangular outline and its anteroposterior and

518   dorsoventral lengths are similar, unlike *Myrmecophaga*, in which the lacrimal is triangular

519   and more anteroposteriorly elongated. The insertion of the jugals is more ventral and

520   posterior than in *Myrmecophaga* and even more than *Tamandua*. Each jugal is slightly

521   tapered by mediolateral compression in its posterior end and it is posterodorsally projected,

522   instead of posteroventrally like *Myrmecophaga*. The posterolateral process of the maxilla

523   contacts the entire anterior and ventral borders of the lacrimal. The orbital ridge is less

524   prominent than in *Myrmecophaga*. The superior orbital wall is laterally expanded, forming

525   a roof more developed than in *Myrmecophaga*. At the orbit level, the palatines are also

526   laterally expanded, forming palatine "wings". These structures make the anterior hard

527   palate look wider than the posterior palate. The posterior end of the hard palate is less

528   ventrally projected, unlike *Tamandua* and *Myrmecophaga*. In lateral view, the squamosal

529   zygomatic processes are dorsally inclined, unlike the ventral inclination of the same bone

530   projection in *Tamandua* and *Myrmecophaga*. This feature would be a convergence with

531   *Cyclopes*. The braincase is proportionally larger than in *Myrmecophaga*, but smaller than in

532   *Tamandua*. The tympanic bulla is less developed than in *Tamandua*. The external auditory

533   meatus has subcircular to circular shape, like *Myrmecophaga* (ovated in *Tamandua*). In *N.*

534   *conspicua* the same opening is located in a posterodorsal position, like *Myrmecophaga* and

535   in contrast with *Tamandua*, in which it has an anterodorsal position. Despite the

536   palatopterygoid suture is not well preserved, appears to be more similar to the irregular

537   suture in *Myrmecophaga*, with a posteriorly opened, asymmetrical "V" shape, than the

538   regular suture in *Tamandua*, with an anteriorly opened, symmetrical "V" shape. There is no

539   interpterygoid vacuity in which it could be established a soft palate, like *Myrmecophaga*.

540   The occipital condyles are proportionally larger than in *Myrmecophaga* [Insert Fig. 5 here].

541

Discussion

Systematic implications

544   This works includes the first description of a new, valid extinct genus for

545   Myrmecophagidae in the last century, i.e. *Myrmedioctes* gen. nov. Likewise, it constitutes a

546   novel taxonomic comprehensive reassessment for *Neotamandua* from Hirschfeld (1976).

547   The results suggest that there are still critical gaps in our knowledge on the composition

548   and diversity of the Neogene assemblages of these xenartrans, particularly in the tropical

549   region of South America. With the inclusion of Gen. et sp. nov. (Fig. 6), Myrmecophagidae

550   now comprises at least five genera (three of them fully extinct) and 11 nominal species

551   (eight extinct species), namely [the dagger means extinct species]: *Protamandua rothi*[†];

552   *Neotamandua? australis*[†]; *Neotamandua borealis*[†]; Gen. et sp. nov.[†]; '*Neotamandua*'

553   *magna*[†]; *Neotamandua greslebini*[†]; *Neotamandua conspicua*[†]; *Myrmecophaga*

554   *caroloameghinoi*[†]; *Myrmecophaga tridactyla*; *Tamandua tetradactyla*; and *Tamandua*

555   *mexicana*. Of these taxa, only two genera and two species have fossil occurrence in

556   northern South America: *N. borealis* (Middle Miocene of Colombia; Hirschfeld 1976) and

557   Gen. et sp. nov. (Middle Miocene of Colombia; this work) (Fig. 7). The latter taxon is a

558   small-to-middle sized myrmecophagid, comparable but slightly smaller than *Tamandua*.

559   The general morphology of the skull of this new anteater resembles more to that of

560   *Tamandua* than any other known taxon. It shows remarkable features such as: (1) strongly

561   tapered nasals toward its anterior rostrum; (2) relatively low rostrum and anterior section of

562   frontals; (3) large pre-orbital section of frontals; and (4) strongly triangulated (anterior)

563   lacrimal. The tapering of nasals is a characteristic in common with *N. conspicua*, but in the

564   latter species the entire rostrum is tapered, not only the nasals, like Gen. et sp. nov. The

565   relatively low rostrum and anterior section of frontals seems to indicate a plesiomorphy,

566   given that this feature is apparently present in *P. rothi*. A large pre-orbital section of

567   frontals is shared, in (nearly) extreme condition, by *N. conspicua* and, especially,

568   *Myrmecophaga*, but it should be noted that in Gen. et sp. nov. there is no such as elongated

569   skull. And, finally, the strongly triangulated (anterior) lacrimal in the latter species is

570   superficially similar to that in *Myrmecophaga*. Estimates of cranial measurements and

571   features (rostrum length, exposure of the maxilla in the orbit and curvature of the

572   basicranial-basifacial axis) used for coding the characters with numbers 4, 8, 9 and 42 of

573   the character list by Gaudin & Branham (1998), allow tentatively infer the phylogenetic

574   position of Gen. et sp. nov. as a taxon included within the clade *Tamandua + Neotamandua*

575   *+ Myrmecophaga* and located in a polytomy with *Tamandua*. Under this preliminary

576   phylogenetic analysis, which is not presented in the results section because there is no

577   enough information for coding the new taxon, *Protamandua* is well supported as the most

578   basal myrmecophagid as consequence of sharing several character states with non-

579   Myrmecophagidae Vermilingua (i.e. *Cyclopes* and *Palaeomyrmidon*; for more details, see

580   Gaudin & Branham 1998). For future studies, it is tentatively suggested the subfamilial

581   name "Myrmecophaginae" for all the Myrmecophagidae more late diverging than

582   *Protamandua*, including possibly Gen. et sp. nov. In this sense, new and more complete

583   material referable to the latter taxon is required to shed light on its phylogenetic position

584   [Insert Fig. 6 here].

585   On other hand, the taxonomic analysis of *Neotamandua* and its referred species indicates

586   that these taxa were based on a poorly supported taxonomy. Other case of extinct

587   vermilinguans with flawed systematics in low levels of the taxonomic hierarchy was noted

588   by McDonald et al. (2008) with regard to genera and species proposed from isolated

589   postcranial elements of putative myrmecophagids or even members of new, distinct

590   families from the Early Miocene of Santa Cruz, southern Argentina. These authors,

591   partially based on comparisons by Hirschfeld (1976), argued that the number of taxa

592   claimed for that area and interval (seven genera and nine species; e.g. *Promyrmephagus*,

593   *Adiastaltus*; Ameghino 1894) has been artificially inflated, even though it is still possible to

594   revalidate taxa other than the well validated species *P. rothi* (McDonald et al. 2008). All

595   these research problems in systematics imply the need to regularly reevaluate the taxonomy

596   of extinct anteaters through reexamination, when possible, of previously described material

597   and the study of new specimens. While it is true that the fossil record of Vermilingua is

598   poor and fragmentary in comparison, for instance, with that of other xenartrans such as

599   Tardigrada, the sampling effort should be increased in order to have greater recovery of

600   fossil material for this group, especially in areas known for their preservation potential (e.g.

601   southern and northwestern Argentina, southwestern Colombia).

602   The reevaluation of the taxonomic status of *Neotamandua* found that there was no

603   diagnosis for this genus. The newly proposed diagnosis includes multiple cranial and

604   potential postcranial characteristics, which uphold that *Neotamandua*, independently

605   whether it is a natural group or not, certainly contains species that do not belong to

606   *Myrmecophaga*, despite their great resemblance with the latter. This outcome is congruent

607   with the taxonomic opinion of Gaudin & Branham (1998) and is at odds with Patterson et

608   al. (1992). Now, can we confidently say that *Neotamandua* is monophyletic from current

609   evidence? *Neotamandua*, as previously defined by other workers, may be composed of

610   successive basal species or genera in relation to the hypothetical clade of *Myrmecophaga*

611   (i.e. *My. tridactyla* + *My. caroloameghinoi*). If that is correct, *Neotamandua* would be

612   paraphyletic by definition, since it excludes some of its descendants (Sereno et al. 1991).

613   This possible pattern of basal paraphyly is consequence of a taxonomy not defined by

614   clades, but grades (Huxley 1958; Wood & Lonergan 2008). The monophyly of

615   *Neotamandua*, as was redefined here (i.e. *N. conspicua* + *N. greslebini* + *N. borealis*), is

616   tentatively supported by three potential synapomorphies shared by two of its species whose

617   postcranium is known (*N. greslebini* and *N. borealis*): (1) sub-oval to gently triangular mid-

618   section of the tibia; (2) ectal and sustentacular facets incipiently connected in the

619   astragalus; (3) short tendinous groove in the lateral side of the calcaneum. However, the

620   synapomorphic condition of these features for *Neotamandua* need to be further tested from

621   systematic analysis of new, more complete and/or associated material of Gen. et sp. nov.

622   and species referred to *Neotamandua*. That would allow to assess more adequately the

623   global morphological variability and character distribution in Miocene myrmecophagids

624   more late diverging than *Protamandua*. In turn, knowing this distribution better, it is more

625   likely to disentangle the taxonomic identities and affinities of the *Neotamandua* species in

626   order to corroborate the monophyly of this genus. For the moment, the hypothesis of

627   Hirschfeld (1976) that *Neotamandua* is not monophyletic is, in principle, less probable if

628   the *species inquirendae* '*N.*' *magna* and *N.*? *australis* are excluded from the genus, as it

629   was decided here, than if they are retained within it. The exclusion of the *species*

630   *inquirendae* does not affect the hypothesis that *Neotamandua* is closer to *Myrmecophaga*

631   than any other known nominal genus. Consequently, the type species of *Neotamandua*, *N.*

632   *conspicua*, is reiterated as closer to *Myrmecophaga* than *Tamandua*, in line with the

633   phylogeny of Gaudin & Branham (1998) and unlike the hypothesis of Carlini & Scillato-

634   Yané (1998).

635   Finally, the material referred to *Neotamandua* sp. and used in this study to make

636   comparisons with *N. borealis*, seems correctly allocated in that genus, but it might

637   eventually be assigned to a new species with very large body size, larger than *N. greslebini*.

638   This is partially conditioned to the clarification of the taxonomic status of '*N.*' *magna*,

639   which is a species comparable in body size to *Neotamandua* sp., so they could be (or not)

640   the same taxon.

641

642   **The diversification of Myrmecophagidae**

643   McDonald et al. (2008) pointed out that since the highly incomplete fossil record of

644   Vermilingua, several fundamental questions on the evolution of this group, including

645   morphological trends and the acquisition of ecological preferences in its distinct taxa, are

646   largely unknown. Likewise, they highlighted some uncertainty related to the divergence

647   times of possible sub-clades. However, several inferences and hypotheses about the

648   evolutionary history of anteaters and, particularly, the myrmecophagids, can be outlined

649   from the current evidence, including that presented in this work. Following to Pascual &

650   Ortiz-Jaureguizar (1990), McDonald et al. (2008) and Toledo et al. (2017), the next

651   discussion is based on multiple palaeobiological, ecological and biogeographical aspects as

652   major constraints and/or consequences of the myrmecophagid evolution.

653   The diversification of Myrmecophagidae was an macroevolutionary event that occurred

654   through the Neogene, at least as early as the Burdigalian (Early Miocene), according to the

655   minimal age estimated for the most basal genus, i.e. *Protamandua*. The beginning of this

656   diversification is approximately overlapped in time with the onset or development of

657   similar events in other higher taxa in South America, such as the xenartrans

658   Megatherioidea, Mylodontidae, Glyptodontidae and Dasypodini (Croft et al. 2007;

659   McDonald & De Iuliis 2008; Bargo et al. 2012; Carlini et al. 2014; Boscaini et al. 2019), or

660   the South American native ungulates Pachyrukhinae, Mesotheriinae and Toxodontidae

661   related to *Pericotoxodon* and *Mixotoxodon* (Seoane et al. 2017; Armella et al. 2018a;

662   Armella et al. 2018b). This pattern shows the importance of the Early Miocene, particularly

663   the Burdigalian, as a critical interval for the diversification of multiple South American

664   land mammal lineages. In light of the geographical provenance of *Protamandua*, the most

665   probable ancestral area for Myrmecophagidae is southern South America (Fig. 7). The

666   palaeonvironmental conditions inferred for the Early Miocene of this area are considerably

667   warmer and more humid (1000☐1500 mm/year) than today, with presence of a subtropical

668   dry forest (Iglesias et al. 2011; Quattrocchio et al. 2011; Kay et al. 2012; Brea et al. 2017;

669   Raigenborm et al. 2018). In line with this reconstruction, Palazzesi et al. (2014), using a

670   rarefied richness analysis from palynological evidence, reported that southern Argentina

671   harboured in the Early Miocene a plant richness comparable to that documented today for

672   the Brazilian Atlantic Forest, in southeastern Brazil. Similar to *Tamandua*, *Protamandua*

673   would have preferred forested habitats and would have had semiarboreal habits (Gaudin &

674   Branham 1998; McDonald et al. 2008; Kay et al. 2012). Whether the ancestral condition of

675   substrate use in Myrmecophagidae is arboreal, as held by Gaudin & Branham (1998), the

676   preference for open biomes (e.g. savannah) and terrestriality in *Myrmecophaga* (and

677 possibly in *Neotamandua*) is a derived condition (McDonald et al. 2008; Toledo et al.

678 2017). The semiarboreal habits of *Tamandua* are explained from niche conservatism or,

679 alternatively, from convergence with *Protamandua* if the ancestor of *Tamandua* was

680 hypothetically terrestrial [Insert Fig. 7 here].

681 Since their particular, low basal metabolic rates and myrmecophagous diets (McNab 1984,

682 1985), it is likely that the global warm recovery during the early Neogene (Early Miocene

683 to early Middle Miocene; including the Middle Miocene Climatic Optimum or MMCO;

684 Fig. 8), linked to latitudinal temperature gradient reduction and expansion of the tropical

685 (warm) forest belt towards higher latitudes in the continents (including South America; see

686 Anderson 2009; Herold et al. 2011; Morley 2011; Palazzesi et al. 2014), has influenced on

687 the evolutionary differentiation of the myrmecophagids, maybe predominantly *in situ* as in

688 the climatically-induced evolution of other small Cenozoic mammals (Fortelius et al.

689 2014), such as *Protamandua*. This differentiation would have been triggered by increase in

690 suitable area in terms of preferred biomes (warm forests in this case) and, especially,

691 temporarily sustained availability of social insects for their feeding (McDonald et al. 2008;

692 Kay et al. 2012; Toledo et al. 2017). Indeed, extant termites and ants (Termitidae and

693 Formicidae, respectively) concentrate the vast majority of their biomass (and species

694 richness) in the tropics and warm subtropical regions (Hölldobler & Wilson 1990; Tobin

695 1995; Davidson & Patrell-Kim 1996; Eggleton et al. 1996; Davidson et al. 2003; Ellwood

696 & Foster 2004; Keller & Gordon 2009). This ecogeographical pattern is consistent with the

697 fossil record of the former higher taxa, which shows a strong tropical niche conservatism

698 from their respective evolutionary origins in the Late Cretaceous/Early Paleogene (see

699 below; Archibald et al. 2011; LaPolla et al. 2013; Guénard et al. 2015; Bourguignon et al.

700 2017).

701 According to Blois & Hadly (2009), the responses of mammalian taxa to climate change

702 throughout the Cenozoic are causally interconnected. These responses at the level of

703 individual taxa may include changes in abundance, genetics, morphology and/or

704 distributional range, and they may instigate multitaxa responses such as diversification

705 events comparable to that placed on the root of the evolutionary tree of Myrmecophagidae.

706 This case of a cladogenetic event possibly induced by climate contrasts in kind of biome

707 with those that have been repeatedly documented for intervals of grassland expansion (e.g.

708 Equidae, Bovidae, Cervidae, Ochotonidae, Hippopotaminae; MacFadden 2000;

709 Bouchenak-Khelladi et al. 2009; Boisserie & Merceron, 2011; Ge et al. 2013).

710 In the Middle Miocene, *N.? australis*, *N. borealis* and Gen. et sp. nov. exhibit a mosaic of

711 morphological features in common with *Tamandua* and/or *Myrmecophaga*, as well as some

712 exclusive characteristics, which suggest an early, important increase in morphological

713 disparity in Myrmecophagidae and possibly the evolutionary divergence of those lineages

714 comprising its crown-group. This coincides with the interpretation of Hirschfeld (1976),

715 according to which the lineages including the extant genera of Myrmecophagidae

716 differentiated morphologically at least from the Friasian (Middle Miocene). Same way, it is

717 compatible with the results of the molecular phylogenies by Delsuc et al. (2001, 2012) and

718 Gibb et al. (2016), which estimated that the evolutionary divergence of *Tamandua* and

719 *Myrmecophaga* occurred in the late Middle Miocene, c. 13 mya. On the other hand, relative

720 body sizes inferred for the Middle Miocene taxa show an apparent trend towards increase in

721 body size in comparison with the basal taxon *Protamandua*. During this interval, the

722   myrmecophagids have a wide geographical distribution in South America (Fig. 7), from

723   low to medium-high latitudes. This is in line with the evolution of larger body sizes since

724   when this attribute increases, the foraging area also increases and, with it, the distributional

725   range, according the general foraging strategy of the extant myrmecophagids (Naples 1999;

726   Toledo et al. 2017; Gaudin et al. 2018). The co-occurrence pattern of *N. borealis* and Gen.

727   et sp. nov. in La Venta area in Colombia constitutes the earliest pattern of this kind for

728   Myrmecophagidae until pending systematic revisions for putative taxa from the Early

729   Miocene of Santa Cruz, Argentina, are carried out. These revisions would allow to

730   determine whether there are two or more co-occurrent myrmecophagid taxa in the latter

731   area. Given that *N. borealis* and Gen. et sp. nov. probably are not sister taxa, it would imply

732   a non-sympatric diversification followed by dispersal of at least one of the involved taxa.

733   The habitat preference of Gen. et sp. nov. in the palaeoenvironmental mosaic of La Venta

734   area (Kay & Madden 1997; Spradley et al. 2019) is speculated as tropical forest

735   (semiarboreal?) by analogy with *Protamandua*, while it is proposed a more generalized

736   habitat selection for *N. borealis* in line with the palaeobiological inference of

737   predominantly terrestrial locomotion for the latter taxon by Hirschfeld (1976). If this hold

738   true, opens the possibility that *N. borealis* is the oldest myrmecophagid inhabiting zones

739   with semi-open or even open vegetation (see below).

740   The morphological and probably taxonomic diversification of Myrmecophagidae continued

741   in the Late Miocene. Inferred body sizes range from larger than *Tamandua* and nearly

742   comparable to *Myrmecophaga*. Considering the wide geographical distribution during the

743   Middle Miocene, there is probably a geographical bias in the fossil record of the

744   myrmecophagids during the Late Miocene as the only known occurrences are

745   *Myrmecophaga*-like forms from northwestern Argentina (Fig. 7). If *N. borealis* and *N.*

746   *greslebini* are sister taxa, as it seems, that means there was a biogeographical connection

747   for Myrmecophagidae between northern and southern South America in the late

748   Middle/early Late Miocene. This inference is congruent with the palaeobiogeographical

749   analyses of Cozzuol (2006) and Carrillo et al. (2015), according to which the affinities

750   between several Late Miocene, northern and southern South American land mammal

751   assemblages are strong or, at least, not so distant as those between Middle Miocene

752   assemblages from the same regions. This pattern might be explained from the geographical

753   shrinks of the Pebas Mega-Wetland System and the Paranean Sea in the Middle-Late

754   Miocene transition (Aceñolaza & Sprechmann 2002; Cozzuol 2006; Salas-Gismondi et al.

755   2015). It is also possible that the expansion of open biomes in South America during the

756   Late Miocene has facilitated this biotic connection, as has been acknowledged in the case

757   of other mammal taxa (e.g. Glyptodontinae, a xenartran group like Myrmecophagidae;

758   Ortiz-Jaureguizar & Cladera 2008; Oliva et al. 2010). Indeed, from a palaeoenvironmental

759   viewpoint, the (partial?) co-occurrence of '*N.*' *magna*, *N. greslebini* and *N. conspicua* in

760   northwestern Argentina is important inasmuch as this pattern is related, for the first time in

761   the evolutionary history of Myrmecophagidae, to savannahs well developed with respect to

762   other kinds of vegetation cover (Latorre et al. 1997; Brandoni et al. 2012; Cotton et al.

763   2014; Amidon et al. 2017; Zimicz et al. 2018). On the basis of the foregoing and by

764   generalization of morphological and ecological features of the living vermilinguans, e.g.

765   less dependence on trees related to greater taxonomic and/or ecological diversity of

766   consumed insects (Hirschfeld 1976; Montgomery 1985a; Rodrigues et al. 2008; Toledo et

767   al. 2017; Table 5), it is hypothesized that, as early as the late Middle Miocene, with the

768   triggering of a global cooling (Fig. 8), *Neotamandua* was involved in a niche evolution

769   process within Myrmecophagidae which implied a significative increase in dietary diversity

770   as myrmecophagous and expansion of substrate use and biome selection. Probably the

771   species of this genus preferred the frequent use of the ground by biomechanical constraints

772   and made inroads into largely open environments as humid savannahs, without excluding

773   use of forested environments, like *Myrmecophaga* (Fuster et al. 2018; Gaudin et al. 2018).

774   The former model is further supported from the evolutionary response pattern to major

775   climatic-vegetational changes documented by Badgley et al. (2008) in a faunal sequence of

776   mammals from the Late Miocene of southern Asia, according to which the trophic niche

777   evolution and, particularly the expansion of this attribute, in conjunction with habitat

778   changes, is related to increase in the probabilities of local and regional survivorship in the

779   studied lineages [Insert Fig. 8 here].

780   On other hand, the fossil record of the crown-group genera, *Tamandua* and *Myrmecophaga*,

781   is confined to the Pliocene-Pleistocene, but the evolutionary (morphological) divergence of

782   *Myrmecophaga* would date back at least to the late Middle Miocene according the first

783   appearance of *Neotamandua*, i.e. *N. borealis*. Under this assumption, the hypothesis of '*N.*'

784   *magna* as a species of *Myrmecophaga* is perfectly feasible. In any case, the biogeographical

785   dynamics of the two extant myrmecophagid genera may have been constrained by their

786   respective ecological tolerances and, they, in turn, by the rapidly changing habitat and

787   biome distribution in the Americas during at least the last five or six million years (de Vivo

788   & Carmignotto 2004; Salzmann et al. 2011; Sniderman et al. 2016; Amidon et al. 2017;

789   Roberts et al. 2018; Grimmer et al. 2018). This applies especially to the case of *Tamandua*

790   since this taxon is less generalist in relation to habitat selection than *Myrmecophaga*

791   (McDonald 2005). Considering the hypothesis of niche expansion for *Neotamandua*, the

792   differentiation of *Myrmecophaga* would have accentuated this putative evolutionary trend

793   through stronger preference for open environments, which is consistent with the general

794   palaeoenvironment of savannah in the Early Pliocene of the area where occurs the oldest

795   species of the latter genus, i.e. *My. caroloameghinoi* (Zavala & Navarro 1993; McDonald et

796   al. 2008).

797   The myrmecophagid evolution has a late episode with the complete formation of the

798   Panama Land Bridge (PLB) in the terminal Neogene (Coates & Stallard 2013; O'dea et al.

799   2016; Jaramillo 2018). *Myrmecophaga tridactyla* invaded and colonized Central- and

800   southern North America (northern Mexico) at least as early as the Early Pleistocene (Shaw

801   & McDonald 1987; Fig. 7). This dispersal event is part of the Great American Biotic

802   Interchange (GABI), specifically the episode referred as GABI 2 (Woodburne 2010).

803   Today, the northern boundary of this species is located in northern Central America, over

804   3000 Km to the south of the northernmost fossil record (Gaudin et al. 2018). This

805   distributional difference was interpreted by Shaw & McDonald (1987) from the occurrence

806   of warmer and more humid conditions in the Early Pleistocene of southern North America

807   (southern United States-northern Mexico) than today in the same area. These conditions

808   would have allowed that *Myrmecophaga* colonize subtropical savannahs with permanent

809   availability of insects included in its diet (Croxen III et al. 2007; McDonald 2005), but

810   subsequent climatic-vegetational shifts (desertification) during the Late Pleistocene would

811   have forced from extirpation a range shrinkage of this taxon towards lower latitudes

812   (McDonald 2005; Ferrusquía-Villafranca et al. 2017). The distributional range pattern of

813   tropical taxa expanded towards southern North America during some intervals of the

814   Pleistocene has been well supported from the records of multiple taxa other than

815   *Myrmecophaga*, including mammals and sauropsids (Shaw & McDonald 1987; Moscato &

816   Jasinski 2016; Ferrusquía-Villafranca et al. 2017).

817   Like *Myrmecophaga*, *Tamandua* also colonized (or evolved in) northern continental

818   territories outside South America. This is supported from the occurrence of *Tamandua* sp.

819   in the terminal Pleistocene of Central Mexico (Arroyo-Cabrales et al. 2004; Ferrusquía-

820   Villafranca et al. 2010; Fig. 7). In its northern zone, the current distributional area of *T.*

821   *mexicana* includes latitudes comparable with that of the referred fossil record for this

822   species (Navarrete & Ortega 2011). Central Mexico is part of the transitional area between

823   the current Neotropical and Neartic regions, called Mexican Transition Zone (MTZ;

824   Halffter & Morrone 2017). All these observations, in conjunction with the above

825   interpretation of the Neogene biogeographical and environmental patterns, suggest that

826   Myrmecophagidae kept throughout its evolutionary history a niche conservatism associated

827   with tropical (warm) habitats (a case of phylogenetic niche conservatism or PNC; see

828   Cooper et al. 2011; Fig. 8), possibly in parallel with the same pattern in species groups of

829   its prey insects (Thompson 1994). Even more, the fact that Myrmecophagidae currently

830   accumulates its highest species richness in the warmest and wettest belt of the Americas

831   (Hayssen 2011; Navarrete & Ortega 2011; Miranda et al. 2017; Gaudin et al. 2018) is

832   further interpreted as evidence that this higher taxon represents support for the tropical

833   niche conservatism hypothesis (TCH; Wiens & Donoghue 2004; Wiens & Graham 2005).

834   However, in line with the discussion above, this major ecological constraint in

835   Myrmecophagidae is not only related to environmental thermal tolerance (see McNab

836   [1985] for an analysis on the thermophysiological constraints of the Xenarthra; McNab

837   [1984] also discussed the same issue for myrmecophagous mammals), as emphasized by

838   TCH, but it is also driven by food availability, at least by limiting or preventing historical

839   colonization of low-productivity regions far from the tropics (Shaw & McDonald 1987;

840   McDonald 2005; Šímová & Storch 2017; Fig. 8).

841

842   Conclusion

843   The systematic evidence presented here suggests that probably the diversification of

844   Myrmecophagidae is taxonomically and biogeographically more complex than previously

845   thought. This insight is based on the description of the new taxon Gen. et sp. nov. for the

846   Middle Miocene of Colombia (co-occurrent species of *N. borealis*) and the determination

847   of *Neotamandua*, as previously defined, as a wastebasket taxon which is probably formed

848   by species belonging to more than one single genus. While Gen. et sp. nov. possibly has

849   affinities with *Tamandua*, more information is needed to test its phylogenetic position

850   within Myrmecophagidae. On the other hand, *N. borealis*, *N. greslebini* and *Neotamandua*

851   sp. share postcranial features (potential synapomorphies) that imply some grade of kinship

852   between them. Therefore, the two nominal species among the former ones are provisionally

853   kept within *Neotamandua*. Alternatively, these features also may constitute

854   symplesiomorphies of a hypothetical lineage which is apparently close to *Myrmecophaga*.

855   The remaining nominal species referred to *Neotamandua*, i.e. '*N.*' *magna* and *N.? australis*

856   were designated as *species inquirendae*. Overall, it is necessary to develop new systematic

857   revisions, including new phylogenetic analyses similar to that of Gaudin & Branham

858   (1998), from new material referable to Gen. et sp. nov. and the referred species to

859   *Neotamandua*, so as to obtain enough evidence to solidly determine the phylogenetic

860   position of the new species from La Venta and corroborate the putative monophyletic status

861   of *Neotamandua*. In line with the foregoing considerations, the paleontological exploration

862   of Neogene sedimentary units in northern South America and northern Argentina is crucial

863   to improve our understanding of the diversification of Myrmecophagidae.

Figure captions

1360 **Figure 1.** Geographical and stratigraphic provenance of the skull VPPLT 975 of the new

1361 taxon described here and the holotype of *Neotamandua borealis* (Hirschfeld 1976). **A**,

1362 location of the Department of Huila in Colombia; **B**, location of the fossil area of interest,

1363 i.e. northern of La Venta area, in the Department of Huila (small rectangle); **C**, location of

1364   the fossil site (black star), near the La Victoria town; **D**, stratigraphic scheme of Guerrero

1365   (1997) for La Venta area, with approximate stratigraphic provenance of VPPLT 975 and

1366   the holotype of *N. borealis*.

1367   **Figure 2.** Cranial measurements used in this work. All are based on Hossotani et al. (2017).

1368   Nomenclatural modifications from these measurements are shown in the section of

1369   Anatomical Abbreviations. **A**, skull of *Tamandua* in dorsal view; **B**, the same skull in

1370   ventral view. **Abbreviations: FL**, frontal length; **GSL**, greatest skull length; **MBW**,

1371   maximum braincase width; **ML**, maxilla length; **NL**, nasal length; **NW**, nasal width; **PL**,

1372   parietal length.

1373   **Figure 3.** Holotypic skull (VPPLT 975) of Gen. et sp. nov. **A**, dorsal view; **B**, right lateral

1374   view; **C**, ventral view; **D**, left lateral view; **E**, anatomical drawing in dorsal view; **F**,

1375   anatomical drawing in right lateral view. **Abbreviations: fr,** frontals; **ji,** jugal insertion; **la,**

1376   lacrimal; **mx,** maxilla; **na,** nasals; **or,** orbit. Scale bar equal to 30 mm.

1377   **Figure 4.** Epitype (FMNH P14419) of *Neotamandua conspicua*. **A**, dorsal view; **B**, right

1378   lateral view; **C**, ventral view; **D**, left lateral view; **E**, right hemimandible; **F**, left

1379   hemimandible; **G**, anatomical drawing in dorsal view; **H**, anatomical drawing in ventral

1380   view; **I**, anatomical drawing in left lateral view. **Abbreviations: ab**, auditory bullae; **fr**,

1381   frontals; **j**, jugal; **mx**, maxilla; **na**, nasals; **oc**, occipital condyles; **pal**, palatines; **ptb**,

1382   pterygoid bullae; **pte**, pterygoids; **szp**, squamosal zygomatic process. Scale bar equal to 80

1383   mm.

1384   **Figure 5.** Two very informative postcranial bones of the holotype (UCMP 39847) of

1385   *Neotamandua borealis* (Hirschfeld 1976). **A**, right astragalus, dorsal view; **B**, right

1386 astragalus, ventral view; **C**, left calcaneum, dorsal view; **D**, left calcaneum, lateral view; **E**,

1387 anatomical drawing of the astragalus in dorsal view; **F**, anatomical drawing of the

1388 astragalus in ventral view; **G**, anatomical drawing of the calcaneum in dorsal view; **H**,

1389 anatomical drawing of the calcaneum in lateral view. **Abbreviations: af**, calcaneal

1390 accessory facet; **ct**, calcaneal tuber; **ef**, ectal facet; **ff**, fibular facet; **h**, astragalar head; **lr**,

1391 lateral ridge; **lt**, lateral trochlea; **mt**, medial trochlea; **sf**, sustentacular facet. Scale bar equal

1392 to 20 mm.

1393 **Figure 6.** Reconstruction the external appearance in life of Gen. et sp. nov. (close-up view).

1394 In the background, individuals of the macraucheniid *Theosodon* (left) and the alouattine

1395 *Stirtonia* (upper right corner) in the tropical forest of La Venta, late Middle Miocene of

1396 Colombia.

1397 **Figure 7.** Geographic and chronological distribution of the myrmecophagid fossil records

1398 during the Late Cenozoic. Note the only two fossil records of these xenartrans outside

1399 South America in the Pleistocene of southern and northern Mexico (*Tamandua* sp. and

1400 *Myrmecophaga tridactyla*, respectively). Based on information compiled by McDonald et

1401 al. (2008). Original references in the same work and, largely, in the main text here.

1402 **Figure 8.** Chronological collation of data on: **A**, biochrons of the myrmecophagid genera or

1403 questionable grouping (horizontal solid bars and dashed line); **B**, distribution of the highest

1404 latitudinal fossil records (northern and/or southern) of myrmecophagids (horizontal solid

1405 bars) and approximate, chronologically discrete latitudinal ranges of tropical rainforest plus

1406 tropical and subtropical dry broadleaf forest (i.e. frost-free areas [mean annual temperatures

1407 higher than 15°C] with significant rainfall, at least seasonally; large vertical rectangles); **C**,

1408 general trend curve of global temperature and climatic episodes during the Late Cenozoic:

1409   **a**, early Neogene warm recovery, including the thermal peak in the late Early-early Middle

1410   Miocene known as Middle Miocene Climatic Optimum or MMCO; **b**, Middle Miocene

1411   climatic transition; **c**, late Middle-Late Miocene cooling; **d**, Early Pliocene warming; **e**,

1412   Late Pliocene-Pleistocene cooling and glaciations. The vertical dashed line indicates the

1413   time of complete formation of the Panama Land Bridge, which represented thereafter a

1414   fundamentally continuous physical connection between South- and North America.

1415   Palaeocological data used for the plot in 'B' is from the following references: Huntley &

1416   Webb III (1988); Toby Pennington et al. (2000); Williams et al. (2004); Williams (2009);

1417   Chan et al. (2011); Morley (2011); Kay et al. (2012); Pound (2012); Pound et al. (2012);

1418   Forrest et al. (2015); Lohmann et al. (2015); Dowsett et al. (2016); Sniderman et al. (2016);

1419   Henrot et al. (2017); Frigola et al. (2018). The temperature curve in 'C' is based on Zachos

1420   et al. (2001, 2008) and it is reproduced with permission.
