### **Detalle de condiciones y parámetros de registración de las estaciones utilizadas de la Red Sismológica Zonal Nuevo Cuyo (RSZNC – INPRES)**

En este apartado se presentan dos tablas que contienen las condiciones de registración de las estaciones sismológicas utilizadas para este estudio y los parámetros de las curvas de respuesta instrumental.

En la tabla A1 se recopila la información brindada por el INPRES acerca de la localización geográfica de las estaciones, sus períodos de funcionamiento, el tipo de roca en el emplazamiento de la instalación para consideraciones del efecto de sitio y la modalidad de envío de datos (analógico o digital) hasta la sede del INPRES en San Juan. Se incluyen además el modelo de sensor empleado, que en estas estaciones puede ser S-13, un modelo corto período de Geotech-Teledyne o GURALP, un sensor banda ancha marca Guralp pero sin especificación del modelo. En algunos casos se indica el modelo de la tarjeta de conversión analógico-digital (CAD). En todas las estaciones, se informan la resolución del digitizador, la frecuencia de muestreo utilizada y el filtro analógico antialias implementado que en general define la banda de paso de la estación dada la frecuencia de muestreo elegida.

En la tabla A2 se presentan los parámetros necesarios para la construcción de las curvas de respuesta de las estaciones utilizando, por ejemplo, el programa *resp.exe* que se incluye en el paquete SEISAN (Havskov y Ottemöller, 2008). A partir de los resultados de calibraciones instrumentales efectuadas por el INPRES, dichos parámetros fueron calculados mediante una subrutina MATHCAD implementada por G. Alguacil (Havskov y Alguacil, 2004). Las curvas de respuesta han sido construidas con el programa *resp* para su empleo en el procesamiento de los datos cada vez que ha sido necesario remover la respuesta instrumental.

*Tabla A.1.- Características de emplazamiento y registración. En cada fila se muestra: código de estación en cuatro letras, nombre de estación, códigos alternativos correspondientes a diferentes intervalos de tiempo o curvas e respuesta, fechas de instalación y desinstalación de equipos si las hubiere, coordenadas, elevación y tipo de rocas en el emplazamiento, modelo de sensor (S-13 es modelo corto período de Geotech-Teledyne y GURALP es marca de sensor e indica banda ancha), formato de telemetría hasta la Central del INPRES, tipo de convertidor analógico digital de acuerdo a marca-diseño de placa de adquisición, resolución en bits y frecuencia del filtro antialiasing. Las frecuencias de muestreo fueron en todos los casos de 100 mps para eventos anteriores al 06/08/1998. Para los datos de eventos posteriores a esa fecha, la frecuencia cambió a 40 mps a excepción de las estaciones RTLL, RTLS, RTCV, ICAZ, CFAZ (no así FO24) que cambiaron a 80 mps. Debido a la existencia de más de un canal de datos y denominación para algunas estaciones, se adoptó una sigla por emplazamiento de estación, manteniéndose los nombres originales de los canales en las extensiones de los archivos ASCII a través de una selección de tres letras de las cuatro que conforman la sigla. En la tabla, los guiones separan nombres o configuraciones de diferentes canales a veces coetáneos, las barras separan configuraciones sucesivas en el tiempo.*

\* Se sabe que dejó de funcionar con la configuración original el 01-Nov-88. Luego se ha vuelto a instalar con la configuración mencionada en la tabla pero dejó de funcionar entre abril y julio de 1996.

\*\* La fecha de inicio corresponde a la instalación de la estación con denominación MO13 (m13), MO14 (m14) se sabe que funcionó además como RTMC hasta abril de 1997.

Tabla A.2.- Constantes de las respuestas de instrumento en desplazamiento a partir de los parámetros listados en la tabla A.1 e incorporados a curvas en formato SEISAN. De izquierda a derecha las columnas contienen código de estación, componente (S por corto período y Z por vertical), período propio del sismómetro, factor de amortiguamiento del sismómetro, constante generadora del sensor, ganancia del amplificador, ganancia promedio del registrador, frecuencia inferior de corte para evitar el paso de DC y número de polos correspondientes, frecuencia superior de corte para evitar el aliasing y número de polos correspondientes, ganancia total en desplazamiento a 1 Hz y a 5 Hz.

## Apéndice B

---

### Catálogo de eventos seleccionados

El catálogo original de sismos está compuesto por eventos con profundidades estimadas a priori tanto superficiales como intermedias y registrados digitalmente por las estaciones de la Red Sismológica Zonal Nuevo Cuyo, INPRES, entre agosto de 1995 a marzo de 1999. Las condiciones impuestas en la selección han sido: una buena relación señal-ruido, amplitudes no saturadas y cudas con duraciones cercanas o superiores a 60s. Estas resultan ser las condiciones básicas para asegurar una base de datos apta para la implementación de las técnicas de análisis de atenuación propuestas. La localización preliminar se ha efectuado en forma individual y con el programa HYPO71. La estructura de velocidad unidimensional de ondas P fue ajustada a los datos mediante la técnica de determinación conjunta de hipocentros y velocidad (JHD) implementada en el programa VELEST (Kissling et al., 1994, Kissling, 1995). Con el modelo de velocidades (Tabla 3.2) y las correcciones de estación (Tabla 3.3) obtenidos se han relocalizado todos los eventos del catálogo original. En la siguiente tabla se presentan los resultados que consisten en 452 eventos localizados con un RMS promedio de 0.16 para un total de 4205 rayos sísmicos analizados.
