## Abstract

We search for a Higgs particle with anomalous couplings in the  $e^+e^- \rightarrow H\gamma$ ,  $e^+e^- \rightarrow HZ$  and  $e^+e^- \rightarrow He^+e^-$  processes with the L3 detector at LEP. We explore the mass range  $70 \text{ GeV} < m_H < 170 \text{ GeV}$  using  $176 \text{ pb}^{-1}$  of integrated luminosity at a center-of-mass energy of  $\sqrt{s} = 189 \text{ GeV}$ . The Higgs decays  $H \rightarrow b\bar{b}$ ,  $H \rightarrow \gamma\gamma$  and  $H \rightarrow Z\gamma$  are considered in the analysis. No evidence for anomalous Higgs production is found. This is interpreted in terms of limits on the anomalous couplings  $d$ ,  $d_B$ ,  $\Delta g_1^Z$  and  $\Delta\kappa_\gamma$ . Limits on the  $\Gamma(H \rightarrow \gamma\gamma)$  and  $\Gamma(H \rightarrow Z\gamma)$  partial widths in the explored Higgs mass range are also obtained. © 2000 Elsevier Science B.V. ## 1. Introduction

The spontaneous symmetry breaking mechanism is a fundamental constituent of the Standard Model (SM) [1] of electroweak interactions. Despite its relevance, the experimental information on the Higgs sector of the SM is scarce and indirect at present. The search for the Higgs particle is a key issue for present and future high-energy colliders, and any deviation from expectations could be a clear guide for new physics scenarios beyond the SM.

The SM can be extended via a linear representation of the  $SU(2)_L \times U(1)_Y$  symmetry breaking

mechanism [2]. The lowest order representation corresponds to the Standard Model, while at higher orders new interactions between the Higgs particle and gauge bosons become possible. They modify the production mechanisms and decay properties of the Higgs. The relevant CP-invariant Lagrangian terms for neutral bosons are the following [3]:

$$\begin{aligned} \mathcal{L}_{\text{eff}} = & g_{H\gamma\gamma} HA_{\mu\nu} A^{\mu\nu} + g_{HZ\gamma}^{(1)} A_{\mu\nu} Z^{\mu\theta\nu} H \\ & + g_{HZ\gamma}^{(2)} HA_{\mu\nu} Z^{\mu\nu} + g_{HZZ}^{(1)} Z_{\mu\nu} Z^{\mu\theta\nu} H \\ & + g_{HZZ}^{(2)} HZ_{\mu\nu} Z^{\mu\nu} + g_{HZZ}^{(3)} HZ_\mu Z^\mu \end{aligned} \quad (1)$$

where  $A_\mu$ ,  $Z_\mu$  and  $H$  are the photon,  $Z$  and Higgs fields, respectively, and  $X_{\mu\nu} = \partial_\mu X_\nu - \partial_\nu X_\mu$ . The couplings  $g_{H\gamma\gamma}$ ,  $g_{HZ\gamma}^{(1)}$ ,  $g_{HZ\gamma}^{(2)}$ ,  $g_{HZZ}^{(1)}$ ,  $g_{HZZ}^{(2)}$  and  $g_{HZZ}^{(3)}$  can be parametrized as follows [4–6]:

$$g_{H\gamma\gamma} = \frac{g}{2m_W} (dsin^2\theta_W + d_B cos^2\theta_W) \quad (2)$$

$$g_{HZ\gamma}^{(1)} = \frac{g}{m_W} (\Delta g_1^Z sin2\theta_W - \Delta\kappa_\gamma tan\theta_W) \quad (3)$$

$$g_{HZ\gamma}^{(2)} = \frac{g}{2m_W} sin2\theta_W (d - d_B) \quad (4)$$

$$g_{HZZ}^{(1)} = \frac{g}{m_W} (\Delta g_1^Z cos2\theta_W + \Delta\kappa_\gamma tan^2\theta_W) \quad (5)$$

$$g_{HZZ}^{(2)} = \frac{g}{2m_W} (d \cos^2 \theta_W + d_B \sin^2 \theta_W) \quad (6)$$

$$g_{HZZ}^{(3)} = \frac{gm_W}{2} \delta_Z \quad (7)$$

where  $g$  is the  $SU(2)_L$  coupling constant,  $\theta_W$  is the weak mixing angle and  $m_W$  is the W mass. The five anomalous couplings  $d$ ,  $d_B$ ,  $\Delta g_1^Z$ ,  $\Delta \kappa_\gamma$  and  $\delta_Z$  constitute a convenient set of adimensional parameters to describe deviations in Higgs–vector boson interactions. They are not severely constrained by electroweak measurements at the Z pole or low energies [3,7]. The couplings  $\Delta g_1^Z$  and  $\Delta \kappa_\gamma$  are commonly used in the context of  $e^+e^- \rightarrow W^+W^-$  studies [5], whereas the couplings  $d$  and  $d_B$  are introduced according to the convention of Ref. [4]. Limits on the parameter  $\xi = (1 + \delta_Z)$ , which quantifies deviations in the magnitude of the  $HZZ$  and  $HW\gamma$  couplings [6] have already been set [8] and will not be discussed in this paper.

A typical signature of anomalous couplings would be a large cross section for a non-standard Higgs production mechanism such as  $e^+e^- \rightarrow H\gamma$ . Another possible effect is the observation of large  $H \rightarrow \gamma\gamma$  and  $H \rightarrow Z\gamma$  branching fractions, which are zero in the SM at tree level. In addition, a search for anomalous Higgs production with non-zero  $\Delta g_1^Z$  or  $\Delta \kappa_\gamma$  couplings offers a complementary way to look for the same type of deviations which may be present in the  $e^+e^- \rightarrow W^+W^-$  process.

The data used in this analysis were collected with the L3 detector [9] at a center-of-mass energy of  $\sqrt{s} = 189$  GeV and correspond to an integrated luminosity of  $176 \text{ pb}^{-1}$ . Previous experimental analyses on anomalous Higgs production accompanied by photons are discussed in Ref. [10].

## 2. Analysis strategy and Monte Carlo samples

We search for a Higgs particle emitted in the  $e^+e^- \rightarrow H\gamma$  and  $e^+e^- \rightarrow He^+e^-$  processes. These processes may be enhanced by the presence of anomalous  $H\gamma\gamma$  and  $HZ\gamma$  couplings and have sensitivity to Higgs masses up to the center-of-mass energy of the collision ( $m_H < \sqrt{s}$ ). The analysis is complemented with a study of the  $e^+e^- \rightarrow HZ$  process, which is sensitive to anomalous  $HZZ$  and  $HZ\gamma$

couplings for Higgs masses below the kinematic limit:  $m_H < \sqrt{s} - m_Z$ . The Feynman diagrams for these three anomalous processes are shown in Fig. 1.

In order to search for the anomalous  $e^+e^- \rightarrow H\gamma$  process (Fig. 1a) a dedicated generator is written. It implements the expected  $(1 + \cos^2 \theta_H) d(\cos \theta_H)$  de-

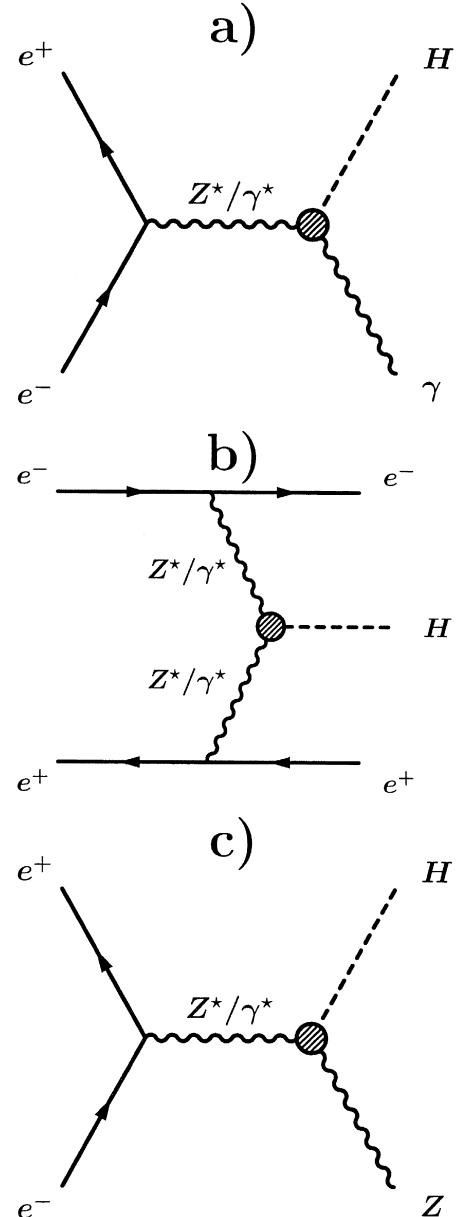

Fig. 1. Relevant processes in the search for  $H\gamma\gamma$ ,  $HZ\gamma$  and  $HZZ$  anomalous couplings at LEP: a)  $e^+e^- \rightarrow H\gamma$ , b)  $e^+e^- \rightarrow He^+e^-$  and c)  $e^+e^- \rightarrow HZ$ .

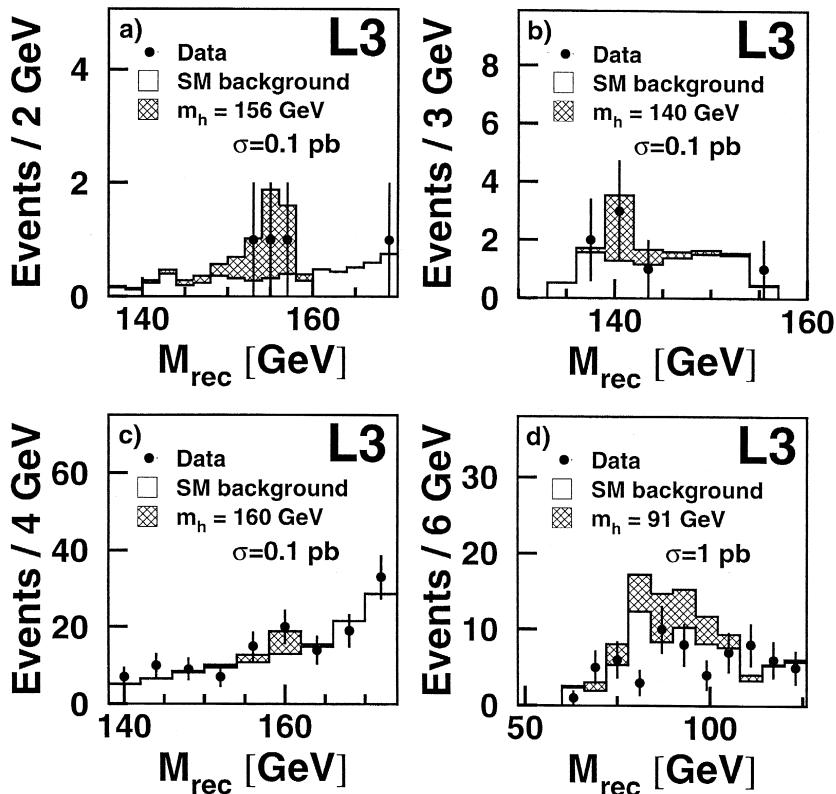

Fig. 2. Distributions of the reconstructed Higgs mass,  $M_{\text{rec}}$ , for a)  $e^+e^- \rightarrow H\gamma\gamma$ , b)  $e^+e^- \rightarrow H\gamma \rightarrow b\bar{b}\gamma$ , c)  $e^+e^- \rightarrow e^+e^-H \rightarrow e^+e^-\gamma\gamma$  and d)  $e^+e^- \rightarrow e^+e^-H \rightarrow e^+e^-b\bar{b}$  event candidates. The data are compared with the MC expectations in the presence of an anomalous Higgs signal. a), b) and c) correspond to Higgs mass hypotheses with a relevant signal significance. d) illustrates the large suppression of  $e^+e^- \rightarrow Z\gamma$  background in the  $e^+e^- \rightarrow e^+e^-H \rightarrow e^+e^-b\bar{b}$  selected sample, as no large peak structure is observed at the  $Z$  mass.

pendence for the differential cross section as a function of the Higgs production angle,  $\theta_H$ . The generator takes into account initial state radiation [11], photon emission by final-state particles [12], spin correlations and off-shell effects in cascade decays like  $H \rightarrow Z\gamma \rightarrow f\bar{f}\gamma$ .

The  $e^+e^- \rightarrow He^+e^-$  process (Fig. 1b) is interpreted as the production of a narrow-width spin-zero resonance (the Higgs particle) in two-photon processes. For the generation of this process, the PC generator [13] is used. The  $e^+e^- \rightarrow HZ$  process, which is also affected by the presence of anomalous

Table 1

Number of selected candidates, background events, signal acceptance and 95% CL cross section limits after the  $e^+e^- \rightarrow H\gamma\gamma$  selection for different Higgs mass hypotheses.

| $m_H$<br>(GeV) | Data<br>events | Background<br>events | Signal<br>acceptance (%) | 95% CL upper limit on<br>$\sigma(e^+e^- \rightarrow H\gamma\gamma) \text{Br}(H \rightarrow \gamma\gamma)$ (fb) |
|----------------|----------------|----------------------|--------------------------|--|
| 70             | 0              | 1.3                  | 22.2                     | 70   |

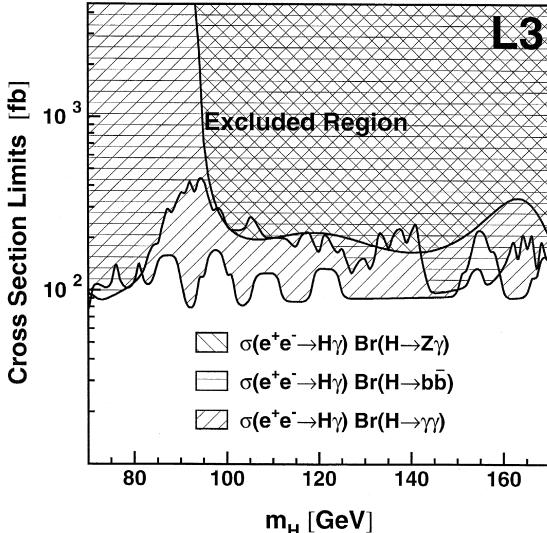

Fig. 3. Cross section 95% CL upper limits as a function of the Higgs mass,  $m_H$ , for the  $e^+e^- \rightarrow H\gamma \rightarrow \gamma\gamma\gamma$ ,  $e^+e^- \rightarrow H\gamma \rightarrow b\bar{b}\gamma$  and  $e^+e^- \rightarrow H\gamma \rightarrow Z\gamma\gamma$  processes in the presence of anomalous Higgs couplings at  $\sqrt{s} = 189$  GeV.

couplings [14] (Fig. 1c), is studied by reinterpreting the cross section limits obtained from the L3 SM [15] and fermiophobic [16] Higgs searches.

The branching fractions and partial widths of an anomalous Higgs are determined according to the calculations of Refs. [17] and [18]. The search is restricted to the Higgs mass range  $70 \text{ GeV} < m_H < 170 \text{ GeV}$ . The decay channels  $H \rightarrow \gamma\gamma$ ,  $H \rightarrow Z\gamma$  and  $H \rightarrow b\bar{b}$  are considered. The cases  $H \rightarrow \gamma\gamma$  and  $H \rightarrow Z\gamma$  complement each other in sensitivity, probing a large part of the parameter space. The  $H \rightarrow b\bar{b}$  decay is dominant in the parameter region where  $H \rightarrow \gamma\gamma$  is strongly suppressed and  $H \rightarrow Z\gamma$  is kinematically forbidden.

| 170            | 10             | 16.0                 | 17.6                     | 157   |

The analysis is performed as a function of the Higgs mass hypothesis. Signal events are generated for the following six Higgs masses: 70, 90, 110, 130, 150 and 170 GeV. For each mass under consideration and for each possible production and decay mode, more than 2000 signal events are generated. For the study of SM backgrounds the following generators are considered: KK2F [19] and PYTHIA [20] for  $e^+e^- \rightarrow q\bar{q}(\gamma)$  contaminations, PYTHIA for multiperipheral  $e^+e^- \rightarrow e^+e^-q\bar{q}$  events, GGG [21] for  $e^+e^- \rightarrow \gamma\gamma(\gamma)$ , KORALW [22] for  $e^+e^- \rightarrow W^+W^-$ , EXCALIBUR [23] for  $e^+e^- \rightarrow W\nu\nu$  and remaining four-fermion backgrounds at high invariant masses, and KORALZ [24] for  $e^+e^- \rightarrow \tau^+\tau^-(\gamma)$ . In all cases the Monte Carlo (MC) statistics used in the analysis is more than 10 times the statistics present in data, except for multiperipheral  $e^+e^- \rightarrow e^+e^-q\bar{q}$  events, for which the relative factor is two.

All MC samples are simulated in the L3 detector and reconstructed in the same way as data. Time-dependent detector inefficiencies are taken into account.

### 3. Event selection

The  $e^+e^- \rightarrow H\gamma$  and  $e^+e^- \rightarrow He^+e^-$  Higgs production mechanisms lead to characteristic topologies. In the  $e^+e^- \rightarrow H\gamma$  process, a high-energy photon of fixed energy is produced, and typically most of the collision energy is visible in the final state. Events originating from a two-photon collision,  $e^+e^- \rightarrow He^+e^-$ , have missing longitudinal momentum and missing mass, as the two emerging electrons tend to escape detection at very low polar angles. The analysis of the specific channel  $e^+e^- \rightarrow H\gamma, H \rightarrow Z\gamma$ , is

Table 3

Signal acceptances and cross section limits after the  $e^+e^- \rightarrow H\gamma \rightarrow Z\gamma\gamma$  selection for different Higgs mass hypotheses.

| $m_H$<br>(GeV) | Signal<br>acceptance (%) | 95% CL upper limit on<br>$\sigma(e^+e^- \rightarrow H\gamma) \text{Br}(H \rightarrow Z\gamma)$ (fb) |
|----------------|--------------------------|---|
| 95             | 9.3                      | 723   |
| 100            | 28.6                     | 234   |
| 110            | 33.5                     | 200   |
| 130            | 36.0                     | 186   |
| 150            | 34.5                     | 194   |
| 170            | 34.2                     | 196   |

based on the  $e^+e^- \rightarrow Z\gamma\gamma$  selection criteria described in Ref. [25]. All analyses are performed in Higgs mass steps of 1 GeV by interpolation of the generated Higgs signal efficiencies. This is particularly relevant in the case of photonic Higgs decays, where the good energy resolution of the L3 detector can be exploited efficiently.

Most of the analyses rely on photon identification. A photon is defined as a shower in the electromagnetic calorimeter with a profile consistent with that of an electromagnetic particle and no associated track in the vertex chamber. The photon candidates must satisfy  $E_\gamma > 5$  GeV and  $|\cos\theta_\gamma| < 0.8$ , where  $E_\gamma$  is the photon energy and  $\theta_\gamma$  is its polar angle. These cuts reduce the background associated to initial and final-state radiation, while keeping a large efficiency for the Higgs signal. The identification of  $H \rightarrow b\bar{b}$  decays is also crucial in this study. The b-tagging performance is similar to the one obtained in the L3 SM Higgs search [26].

### 3.1. $e^+e^- \rightarrow H\gamma \rightarrow \gamma\gamma\gamma$ analysis

In order to select  $e^+e^- \rightarrow H\gamma \rightarrow \gamma\gamma\gamma$  events we require three photon candidates with a total electro-

magnetic energy larger than  $\sqrt{s}/2$ . In addition, the invariant mass of at least one of the photon pairs in the event must be consistent with the Higgs mass hypothesis within 3 GeV.

After these cuts the contamination from processes other than  $e^+e^- \rightarrow \gamma\gamma(\gamma)$  is estimated to be negligible. Fig. 2a presents the distribution of the invariant mass in data and in MC for one of the Higgs mass hypotheses with largest signal significance.

The number of expected and observed events, the signal efficiency in the full phase space, and the limit on  $\sigma(e^+e^- \rightarrow H\gamma) \text{Br}(H \rightarrow \gamma\gamma)$  are shown in Table 1 for several Higgs mass hypotheses. No evidence for any anomalous signal is observed, leading to the 95% confidence level (CL) limits shown in Fig. 3. Throughout this paper, a Bayesian approach with a flat prior distribution is adopted in the derivation of the limits on the signal cross section.

### 3.2. $e^+e^- \rightarrow H\gamma \rightarrow b\bar{b}\gamma$ analysis

High particle multiplicity and momentum imbalance cuts are applied in order to select an initial sample of hadronic events. A  $b\bar{b}\gamma$  event is tagged by the presence of an isolated photon and b-hadrons

Table 4

Number of selected candidates, background events, signal acceptances and limits on  $\Gamma(H \rightarrow \gamma\gamma) \text{Br}(H \rightarrow \gamma\gamma)$  from the  $e^+e^- \rightarrow e^+e^- H \rightarrow e^+e^-\gamma\gamma$  selection for different Higgs mass hypotheses.

| $m_H$<br>(GeV) | Data<br>events | Background<br>events | Signal<br>acceptance (%) | 95% CL upper limit on<br>$\Gamma(H \rightarrow \gamma\gamma) \text{Br}(H \rightarrow \gamma\gamma)$ (MeV) |

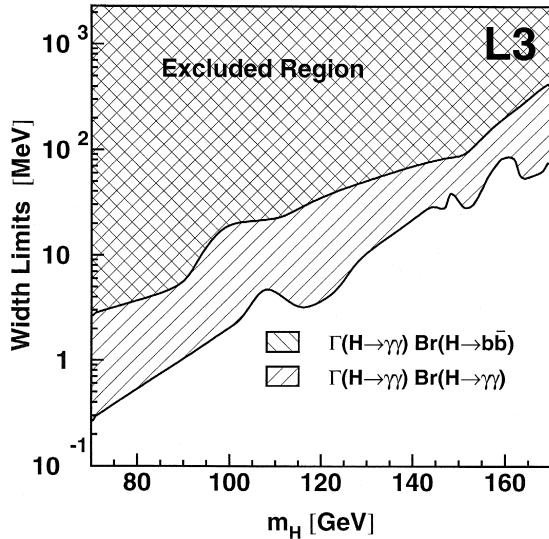

Fig. 4. Upper limits at the 95% CL on the quantities  $\Gamma(H \rightarrow \gamma\gamma)\text{Br}(H \rightarrow \gamma\gamma)$  and  $\Gamma(H \rightarrow \gamma\gamma)\text{Br}(H \rightarrow b\bar{b})$  as a function of the Higgs mass,  $m_H$ , from the analysis of the  $e^+e^- \rightarrow He^+e^-$  process in the presence of anomalous Higgs couplings at  $\sqrt{s} = 189\text{ GeV}$ .

(the event b-tag discriminant,  $B_{\text{tag}}$  [26], must exceed 1.5).

The contamination in the selected sample is dominated by the almost irreducible  $e^+e^- \rightarrow Z\gamma$  process. The remaining backgrounds are estimated to be at the 1% level. The number of expected and observed events and the signal acceptance in the full phase space are shown in Table 2 for several Higgs mass hypotheses.

The distribution of the mass recoiling to the photon in data and in MC for one of the Higgs mass hypotheses with largest signal significance is plotted

in Fig. 2b. This distribution is used to set upper limits on the magnitude of  $\sigma(e^+e^- \rightarrow H\gamma)\text{Br}(H \rightarrow b\bar{b})$ . There is good agreement between data and MC in the absence of a Higgs signal, leading to the limits shown in Table 2 and Fig. 3.

### 3.3. $e^+e^- \rightarrow H\gamma \rightarrow Z\gamma\gamma$ analysis

The selection criteria for this channel are the same as those used for the measurement of the  $e^+e^- \rightarrow H\gamma \rightarrow Z\gamma\gamma$  cross section [25]. We select 36 events, in agreement with the expected SM background of 39.2. The signal efficiency over the full phase space and the upper limits on  $\sigma(e^+e^- \rightarrow H\gamma)\text{Br}(H \rightarrow Z\gamma)$  are shown in Table 3 and Fig. 3.

### 3.4. $e^+e^- \rightarrow He^+e^-$ , $H \rightarrow \gamma\gamma$ analysis

The selection of the  $e^+e^- \rightarrow e^+e^-H \rightarrow e^+e^-\gamma\gamma$  signal requires the presence of two photon candidates in the event. In addition, a kinematic fit to the signal hypothesis is performed. We assume that all the missing energy is lost in the beam pipe and that the visible mass of the event is consistent with  $m_H$  within the experimental uncertainties. Finally, a cut on the  $\chi^2$  of this fit is applied.

The distribution of the two photon invariant mass for data and MC after the kinematic fit is shown in Fig. 2c for one of the Higgs mass hypotheses. The background is dominated by  $e^+e^- \rightarrow \gamma\gamma(\gamma)$  events. Since  $\sigma(e^+e^- \rightarrow He^+e^-)$  is proportional to the partial Higgs width into photons,  $\Gamma(H \rightarrow \gamma\gamma)$ , the cross section limits are directly interpreted in terms of  $\Gamma(H \rightarrow \gamma\gamma)\text{Br}(H \rightarrow \gamma\gamma)$ . The number of expected and observed events and the signal efficiency over

Table 5

the full phase space are listed in Table 4 for several Higgs mass hypotheses. There is no evidence for any anomalous signal, leading to the 95% CL limits presented in Table 4 and in Fig. 4.

### 3.5. $e^+e^- \rightarrow He^+e^-$ , $H \rightarrow b\bar{b}$ analysis

Particle multiplicity and transverse momentum imbalance cuts are applied in order to select an initial sample of hadronic events. Most of the  $e^+e^- \rightarrow e^+e^-q\bar{q}$  background is rejected by requiring a visible event mass greater than 50 GeV. The b-quark purity is increased by a cut on the event tag discriminant ( $B_{tag} > 2$ ). Events are constrained to two jets by means of the Durham algorithm [27]. Those events with a  $y_{23}$  value in excess of 0.05 are rejected, where  $y_{23}$  is the jet resolution parameter for which the transition from two to three jets occurs. As for the  $e^+e^- \rightarrow e^+e^-H \rightarrow e^+e^-\gamma\gamma$  case, a kinematic fit is performed. A final cut on missing mass after the kinematic fit,  $M_{\text{miss}}$ , is required in order to reject a large fraction of the  $e^+e^- \rightarrow b\bar{b}\gamma$  background. For Higgs masses above 95 GeV, we require  $M_{\text{miss}} > 0.09\sqrt{s}$ . For lower Higgs masses this requirement is tightened to  $M_{\text{miss}} > 0.44\sqrt{s}$  to further reject the  $e^+e^- \rightarrow Z\gamma$  contamination. Fig. 2d shows the invariant mass distribution of the selected events for the  $m_H = m_Z$  hypothesis after kinematic fit.

After these cuts, the remaining background corresponds mostly to  $e^+e^- \rightarrow q\bar{q}(\gamma)$  events, with a small contribution from  $e^+e^- \rightarrow W^+W^-$  and  $e^+e^- \rightarrow e^+e^-q\bar{q}$  events. The  $\chi^2$  distribution of the kinematic fit shows the largest sensitivity to the signal and is used to set the limits on  $\Gamma(H \rightarrow \gamma\gamma)\text{Br}(H \rightarrow b\bar{b})$  presented in Table 5 and Fig. 4.

## 4. Limits on anomalous couplings

The analyses performed over the different Higgs production mechanisms and decay channels show that the experimental data agree with the SM MC predictions. This agreement is quantified in terms of limits on the anomalous parameters  $d$ ,  $d_B$ ,  $\Delta g_1^Z$  and  $\Delta\kappa_\gamma$ .

### 4.1. One-dimensional limits

Exclusion limits for each individual coupling are derived as a function of the Higgs mass following

criteria similar to the ones employed in the SM Higgs search [8]. For a given coupling  $x$ , a point in the  $(m_H, x)$  plane is considered as excluded at the 95% CL or more if the ratio of the confidence level

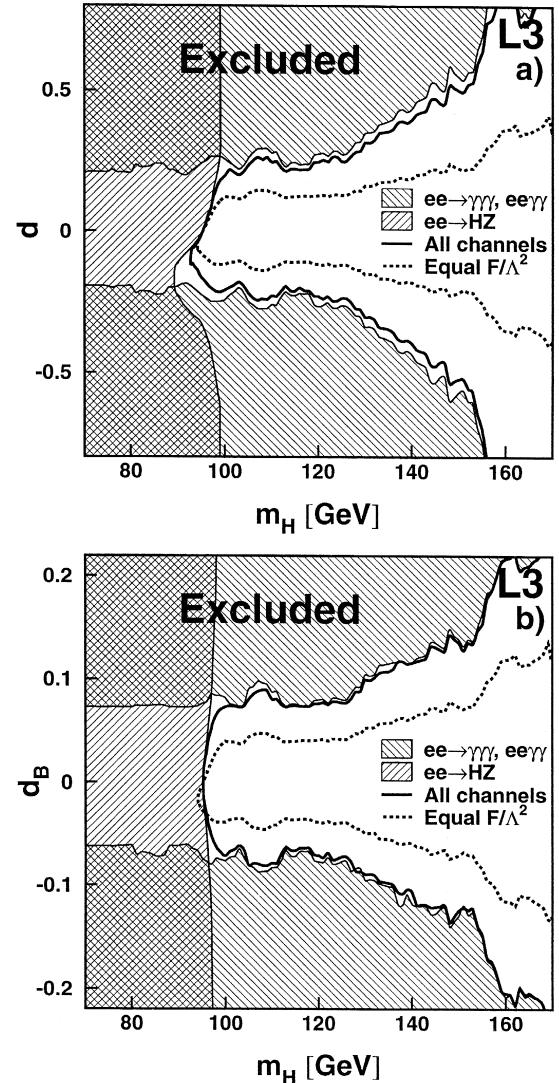

Fig. 5. Excluded regions for the anomalous couplings a)  $d$  and b)  $d_B$  as a function of the Higgs mass  $m_H$ . Limits on  $d$  are obtained under the assumption  $d_B = \Delta g_1^Z = \Delta\kappa_\gamma = 0$ , while limits on  $d_B$  assume the relation  $d = \Delta g_1^Z = \Delta\kappa_\gamma = 0$ . The regions excluded by the most sensitive analyses:  $e^+e^- \rightarrow H\gamma \rightarrow \gamma\gamma\gamma$ ,  $e^+e^- \rightarrow e^+e^-H \rightarrow e^+e^-\gamma\gamma$  and  $e^+e^- \rightarrow HZ$  are also shown. In addition, we show the limits reached under the assumption of equal couplings at the scale of new physics  $\Lambda$  (dashed lines) as described in the text.

for the ‘signal + background’ hypothesis to the confidence level for the ‘background-only’ hypothesis is less than 0.05. In this study all other couplings are assumed to be zero.

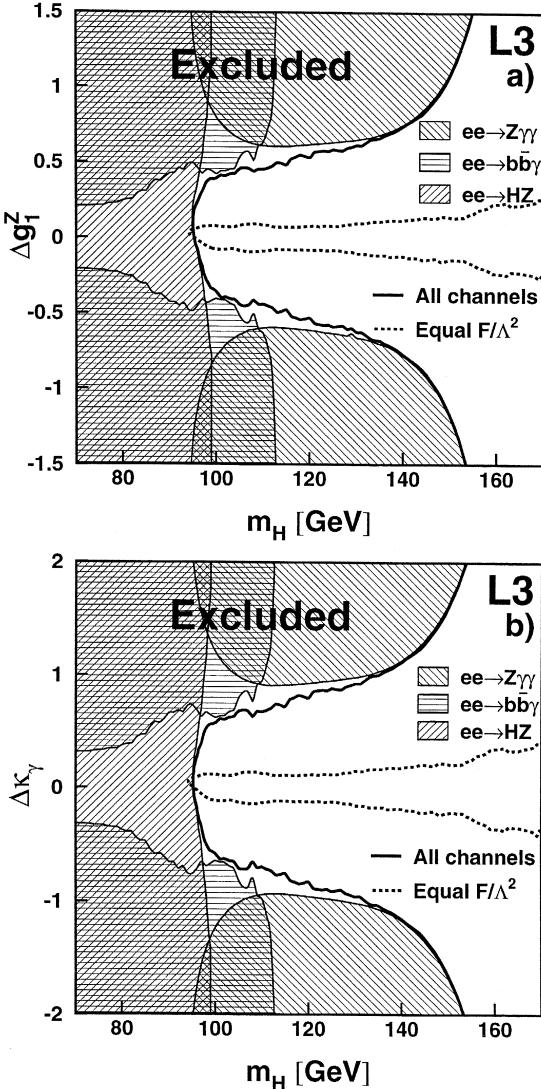

Fig. 6. Excluded regions for the anomalous couplings a)  $\Delta g_1^Z$  and b)  $\Delta \kappa_\gamma$  as a function of the Higgs mass  $m_H$ . Limits on  $\Delta g_1^Z$  are obtained under the assumption  $d = d_B = \Delta \kappa_\gamma = 0$ , while limits on  $\Delta \kappa_\gamma$  assume the relation  $d = d_B = \Delta g_1^Z = 0$ . The regions excluded by the most sensitive analyses:  $e^+ e^- \rightarrow H\gamma \rightarrow Z\gamma\gamma$ ,  $e^+ e^- \rightarrow H\gamma \rightarrow b\bar{b}\gamma$  and  $e^+ e^- \rightarrow HZ$  are also shown. In addition, we show the limits reached under the assumption of equal couplings at the scale of new physics  $\Lambda$  (dashed lines) as described in the text.

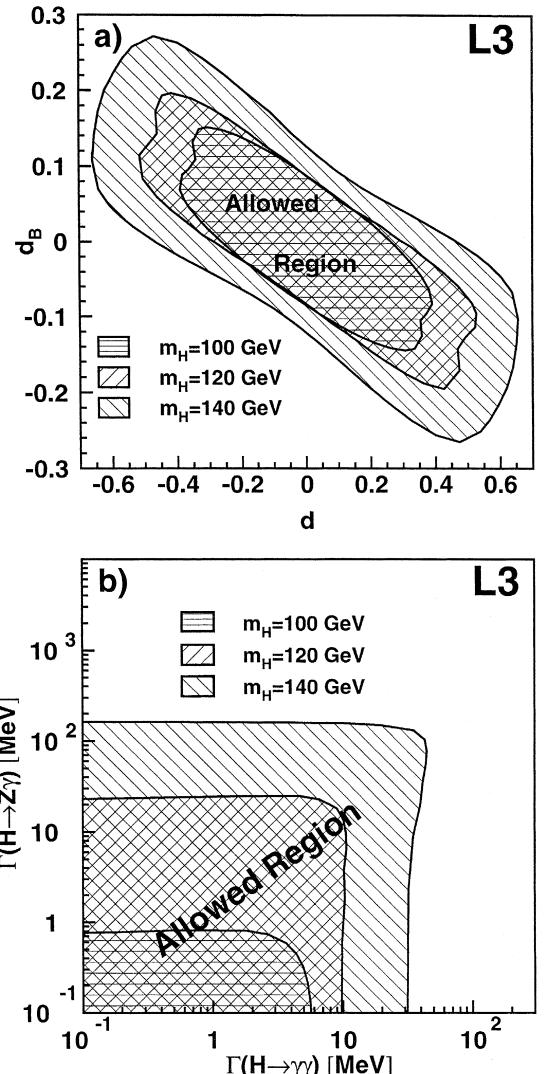

Fig. 7. Allowed regions at more than 95% CL in the a) ( $d, d_B$ ) and b) ( $\Gamma(H \rightarrow \gamma\gamma), \Gamma(H \rightarrow Z\gamma)$ ) planes for different Higgs mass assumptions. All analyzed channels are used. The results are consistent with the SM expectations:  $d \approx d_B \approx 0$  and  $\Gamma(H \rightarrow \gamma\gamma) \approx \Gamma(H \rightarrow Z\gamma) \approx 0$ .

The results for the four parameters:  $d, d_B, \Delta g_1^Z$  and  $\Delta \kappa_\gamma$  are shown in Figs. 5 and 6. In addition to the combined results obtained using all processes under study, the individual results for the most sensitive channels are also displayed.

In all cases, the  $e^+ e^- \rightarrow HZ$  searches are enough to exclude the region  $m_H \lesssim \sqrt{s} - m_Z$  for any value of the anomalous coupling. The fermiophobic  $e^+ e^-$

$\rightarrow \text{HZ}, \text{H} \rightarrow \gamma\gamma$  search is sensitive to large values of  $d$  and  $d_B$ , for which there is an enhancement of the  $\text{H} \rightarrow \gamma\gamma$  branching fraction. The standard search for  $e^+e^- \rightarrow \text{HZ}, \text{H} \rightarrow b\bar{b}, \tau^+\tau^-$  covers the region  $d \approx d_B \approx 0$ .

The  $e^+e^- \rightarrow \text{H}\gamma \rightarrow \gamma\gamma\gamma$  and  $e^+e^- \rightarrow e^+e^- \text{H} \rightarrow e^+e^- \gamma\gamma$  channels are sensitive to large values of the  $\text{H}\gamma\gamma$  couplings, i.e. to large values of the combination  $d \sin^2\theta_W + d_B \cos^2\theta_W$  (Fig. 5). On the contrary, the  $e^+e^- \rightarrow \text{H}\gamma \rightarrow Z\gamma\gamma$  process has a dominant role when  $\text{H} \rightarrow \gamma\gamma$  is suppressed (Fig. 6). This is the case for the fits to  $\Delta g_1^Z$  and  $\Delta\kappa_\gamma$  in the Higgs mass range  $m_Z < \sqrt{s} < 2m_W$ . The sensitivity of the  $e^+e^- \rightarrow \text{H}\gamma \rightarrow b\bar{b}\gamma$  channel (Fig. 6 at  $m_H \approx m_Z$ ) concerns the region in which  $\text{H} \rightarrow \gamma\gamma$  is small, the  $\text{HZ}\gamma$  coupling is large and the  $\text{H} \rightarrow Z\gamma$  decay is kinematically not possible. The reduced sensitivity of the  $e^+e^- \rightarrow e^+e^- \text{H} \rightarrow e^+e^- b\bar{b}$  process is due to the strong decrease of the  $\text{H} \rightarrow bb$  branching fraction in the presence of large  $\text{H}\gamma\gamma$  couplings.

The sensitivity of the analysis degrades rapidly when  $m_H$  approaches the  $2m_W$  threshold, where the  $\text{H} \rightarrow W^+W^-$  decay becomes dominant even in the presence of relatively large anomalous couplings.

Another usual assumption [3] is to consider that all anomalous interactions have the same strength  $F$  at the scale of new physics  $\Lambda$ , i.e.  $m_W^2 F/\Lambda^2 = \Delta\kappa_\gamma = -d = -d_B/\tan^2\theta_W = 2\cos^2\theta_W \Delta g_1^Z$ . This choice, although reasonable in what concerns orders of magnitude, is very particular. It implies the absence of an anomalous  $\text{H} \rightarrow Z\gamma$  decay and a large exclusion power for the channels sensitive to the  $\text{H}\gamma\gamma$  coupling. We show the excluded regions under this assumption in Figs. 5 and 6.

#### 4.2. Two-dimensional limits

The 95% CL contours obtained from a likelihood fit in the  $(d, d_B)$  plane, taking into account all analyzed processes, are shown in Fig. 7 for different Higgs masses. In this fit we assume that the couplings  $\Delta g_1^Z$  and  $\Delta\kappa_\gamma$  are zero. The  $e^+e^- \rightarrow \text{H}\gamma \rightarrow Z\gamma\gamma$  process helps in excluding large values of the anomalous couplings in the region where  $d \sin^2\theta_W + d_B \cos^2\theta_W \approx 0$ . The fit is reinterpreted as a fit in the  $(\Gamma(\text{H} \rightarrow \gamma\gamma), \Gamma(\text{H} \rightarrow Z\gamma))$  plane. The results are also presented in Fig. 7 for different Higgs masses.

#### Acknowledgements

We wish to express our gratitude to the CERN accelerator divisions for the excellent performance of the LEP machine. We acknowledge the contributions of the engineers and technicians who have participated in the construction and maintenance of this experiment.
